Overview

The HP 1910 Switch Series can be configured through the command line interface (CLI), Web interface, and SNMP/MIB. These configuration methods are suitable for different application scenarios.

- The Web interface supports all 1910 Switch Series configurations.
- The CLI provides configuration commands to facilitate your operation. To perform other configurations not supported by the CLI, use the Web interface.

Configuring the switch in the Web interface

The device provides web-based configuration interfaces for visual device management and maintenance.

Figure 1 Web-based network management operating environment

Restrictions and guidelines

To ensure a successful login, verify that your operating system and Web browser meet the requirements, and follow the guidelines in this section.

Operating system requirements

- The device supports the following operating systems:
 - Linux
 - MAC OS
 - Windows 2000
 - Windows Server 2003 Enterprise Edition
 - Windows Server 2003 Standard Edition
 - Windows Vista
 - Windows XP
- If you are using a Windows operating system, turn off the Windows firewall. The Windows firewall limits the number TCP connections. When the limit is reached, you cannot log in to the Web interface.

Web browser requirements

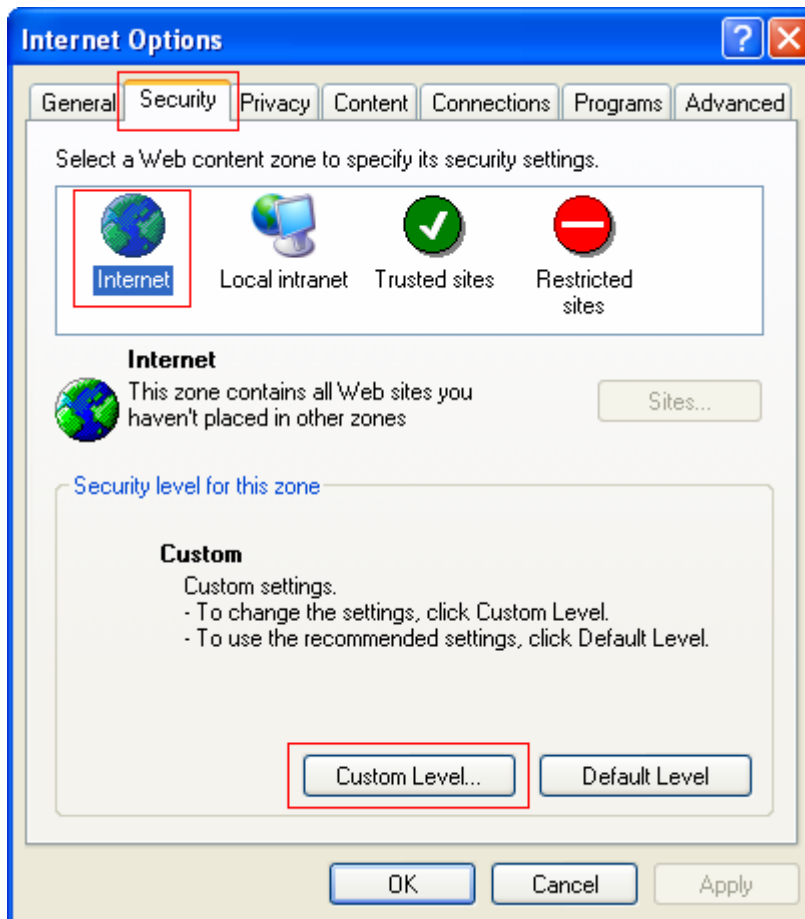

- The device supports the following Web browsers:
 - Google Chrome 2.0.174.0 or higher
 - Microsoft Internet Explorer 6.0 SP2 or higher
 - Mozilla Firefox 3.0 or higher
- If you are using a Microsoft Internet Explorer browser, you must enable the security settings (see "[Enabling securing settings in a Microsoft Internet Explorer browser](#)"), including **Run ActiveX controls and plug-ins**, **Script ActiveX controls marked safe for scripting**, and **Active scripting**.
- If you are using a Mozilla Firefox browser, you must enable JavaScript (see "[Enabling JavaScript in a Firefox browser](#)").

Enabling securing settings in a Microsoft Internet Explorer browser

1. Launch the Internet Explorer, and select **Tools > Internet Options** from the main menu.

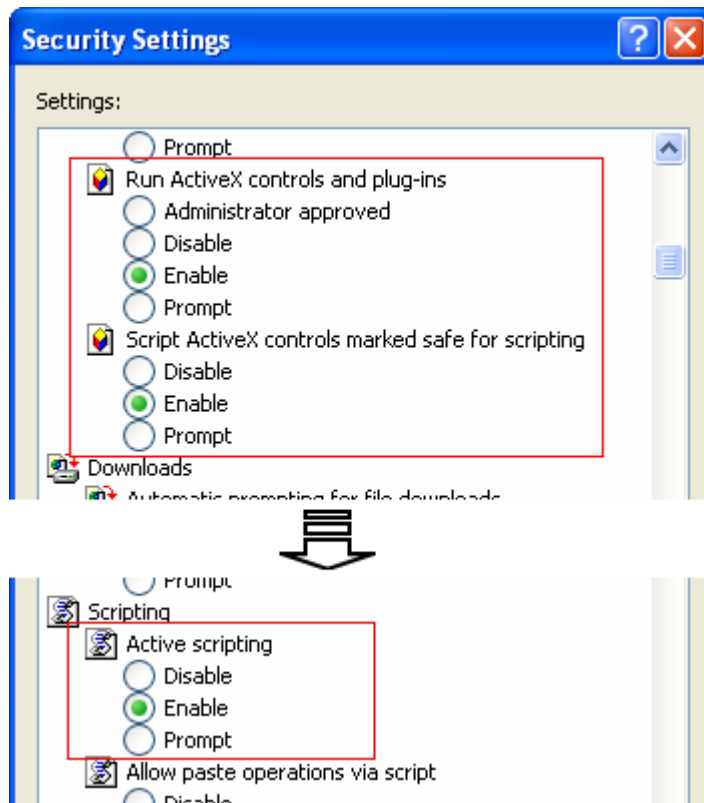

2. Click the **Security** tab, and select the content zone where the target Website resides, as shown in Figure 2.

Figure 2 Internet Explorer settings (1)

3. Click **Custom Level**.
4. In the **Security Settings** dialog box, enable **Run ActiveX controls and plug-ins**, **Script ActiveX controls marked safe for scripting**, and **Active scripting**.

Figure 3 Internet Explorer settings (2)

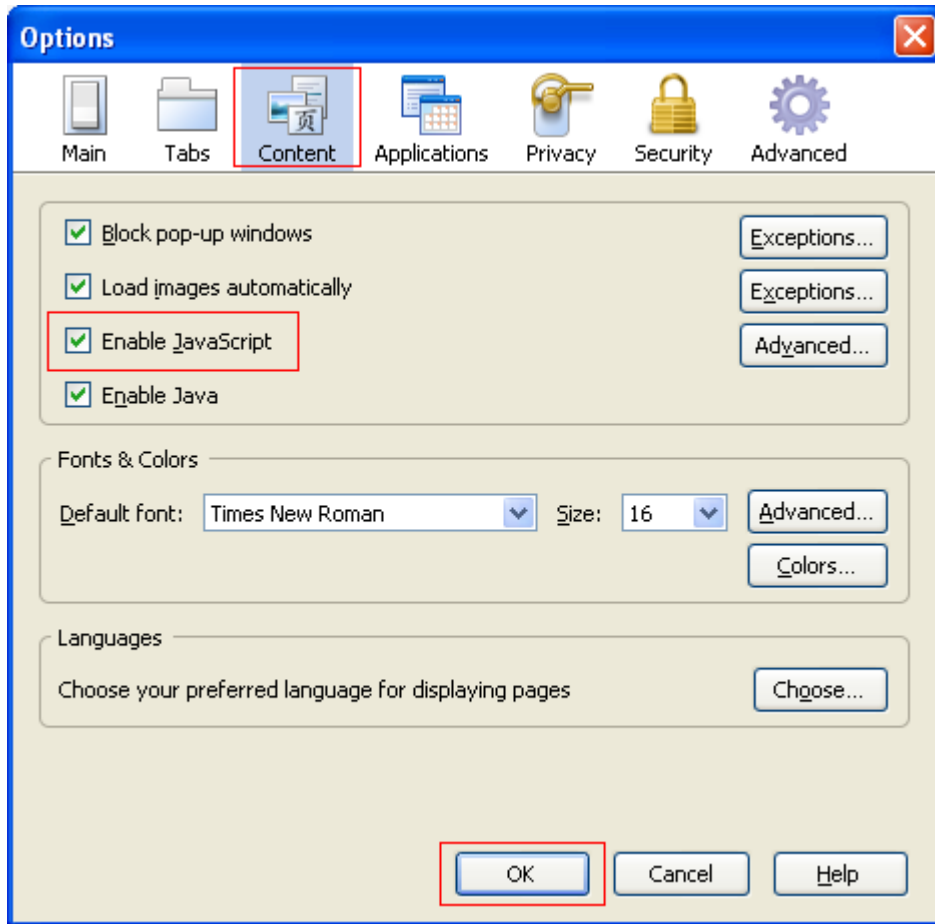

5. Click **OK** to save your settings.

Enabling JavaScript in a Firefox browser

1. Launch the Firefox browser, and select **Tools > Options**.
2. In the **Options** dialog box, click the **Content** icon, and select **Enable JavaScript**.

Figure 4 Firefox browser settings

3. Click **OK** to save your settings.

Others

- Make sure the management PC and the device can reach each other.
- Do not use the **Back**, **Next**, **Refresh** buttons provided by the browser. Using these buttons might result in Web page display problems.
- To ensure correct display of Web page contents after software upgrade or downgrade, clear data cached by the browser before you log in.
- If you click the verification code displayed on the Web login page, you can get a new verification code.
- Up to 5 users can concurrently log in to the device through the Web interface.
- After logging in to the Web interface, you can select **Device > Users** from the navigation tree, create a new user, and select **Wizard** or **Network > VLAN interface** to configure the IP address of the VLAN interface acting as the management interface.

Logging in to the Web interface for the first time

When you log in to the Web interface for the first time, perform the following tasks:

1. [Logging in to the Web interface by using the default username](#)

2. Creating an admin user
3. Deleting the default username

Logging in to the Web interface by using the default username

You can use the following default settings to log in to the web interface through HTTP:

- **Username**—admin.
- **Password**—None.
- **IP address of VLAN-interface 1 on the device**—Default IP address of the device, depending on the status of the network where the device resides.
 - If the device is not connected to the network, or no DHCP server exists in the subnet where the device resides, you can get the default IP address of the device on the label on the device, as shown in [Figure 5](#). The default subnet mask is 255.255.0.0.

Figure 5 Default IP address of the device

Default IP Address: 169.254.52.86

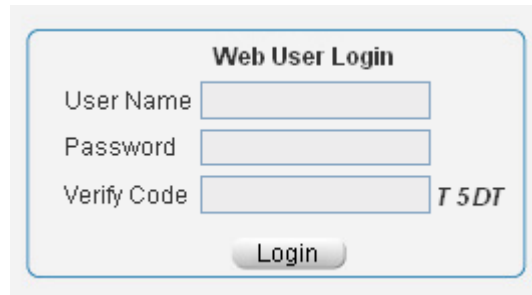

- If a DHCP server exists in the subnet where the device resides, the device will dynamically obtain its default IP address through the DHCP server. You can log in to the device through the console port, and execute the **summary** command to view the information about its default IP address.

```
<Sysname> summary
Select menu option:      Summary
IP Method:               DHCP
IP address:               10.153.96.86
Subnet mask:              255.255.255.0
Default gateway:          0.0.0.0
<Omitted>
```

Assuming that the default IP address of the device is 169.254.52.86, to log in to the Web interface of the device from a PC:

1. Connect the GigabitEthernet interface of the device to a PC by using a crossover Ethernet cable. By default, all interfaces belong to VLAN 1.
2. Configure an IP address for the PC and make sure that the PC and device can reach each other. For example, assign the PC an IP address (for example, 169.254.52.1) within 169.254.0.0/16 (except for the default IP address of the device).
3. Open the browser, and input the login information.
 - a. Type the IP address `http:// 169.254.52.86` in the address bar and press **Enter**.
The login page of the web interface (see [Figure 6](#)) appears.
 - b. Enter the username **admin** and the verification code, leave the password blank, and click **Login**.

Figure 6 Login page of the Web interface

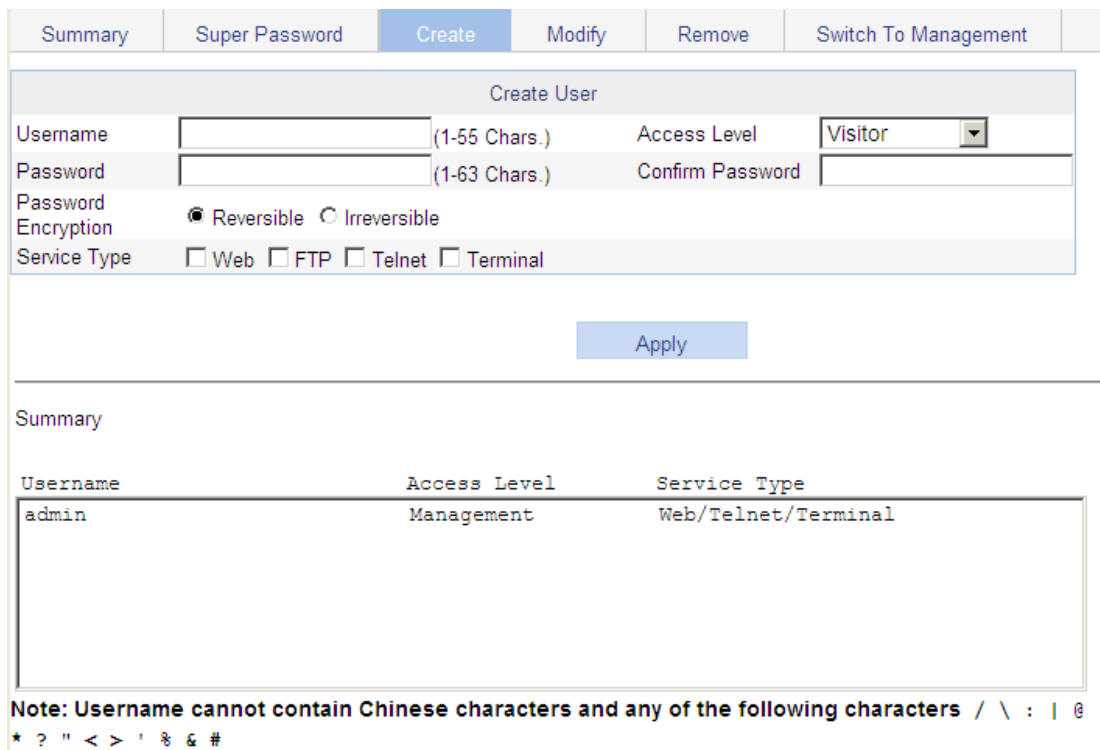

The image shows a 'Web User Login' form. It contains three input fields: 'User Name', 'Password', and 'Verify Code'. To the right of the 'Verify Code' field is a timestamp 'T 5DT'. Below the input fields is a 'Login' button.

Creating an admin user

1. Select **Device > Users** from the navigation tree.
2. Click the **Create** tab.

Figure 7 Creating an admin user

The image shows the 'Create User' form in a web interface. The form has a tabbed interface with tabs: 'Summary', 'Super Password', 'Create' (selected), 'Modify', 'Remove', and 'Switch To Management'. The 'Create' tab contains the following fields:

- Username**: Input field with a note '(1-55 Chars.)'
- Access Level**: Dropdown menu with 'Visitor' selected.
- Password**: Input field with a note '(1-63 Chars.)'
- Confirm Password**: Input field.
- Password Encryption**: Radio buttons for 'Reversible' (selected) and 'Irreversible'.
- Service Type**: Checkboxes for 'Web', 'FTP', 'Telnet', and 'Terminal'.

Below the form is an 'Apply' button. Below the 'Apply' button is a 'Summary' section showing the created user:

Username	Access Level	Service Type
admin	Management	Web/Telnet/Terminal

Below the summary table is a note: **Note: Username cannot contain Chinese characters and any of the following characters** / \ : | @ * ? " < > ' & #

3. Set a username and password. Select **Management** from the access level list. Select at least one service type.
4. Click **Apply**.
5. Click **Save** in the upper right corner of the page and click **OK**.
6. Click **Logout** in the upper right corner of the page.

NOTE:

Set a password with high complexity. Make sure you remember the username and password.

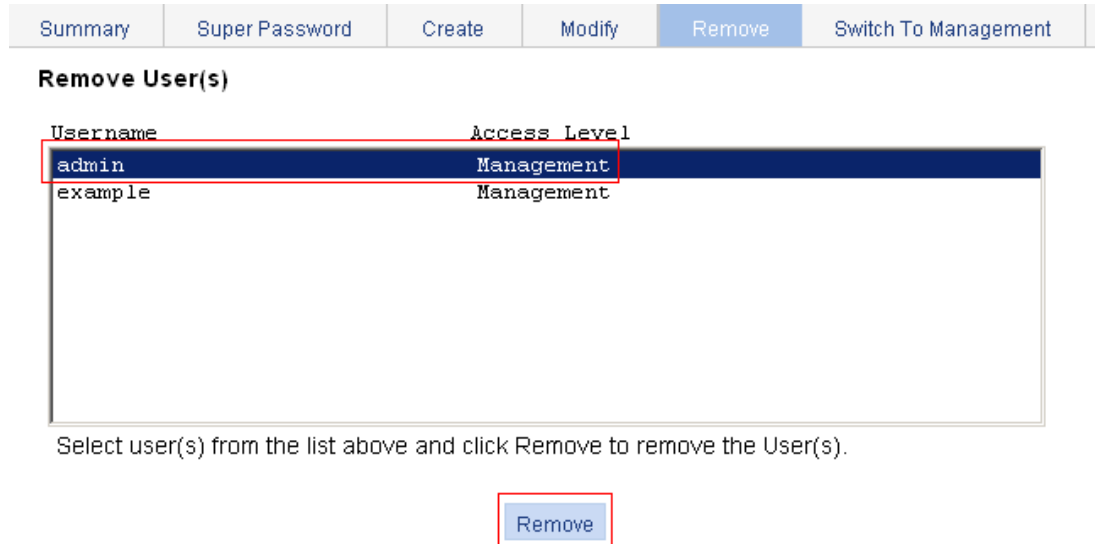

Deleting the default username

For security purposes, delete the default username after you create and save the new admin user.

To delete the default user name:

1. Log in to the Web interface as an admin.
2. Select **Device > Users** from the navigation tree, and click the **Remove** tab.

Figure 8 Deleting the default username

3. Select the default username **admin**, and click **Remove**.
4. On the dialog box that appears, click **OK**.

Logging in to the Web interface

To log in to the Web interface:

1. Open the browser, type the address, and press **Enter**.
2. Enter the username, password, and the verification code, and click **Login**, as shown in [Figure 6](#).

NOTE:

- Up to 5 users can concurrently log in to the device through the Web interface.
- You can log in to the Web interface through HTTP or HTTPS. To use HTTPS, enable it and enter a URL starting with **https://**. For more information, see "[Managing services](#)."

Logging out of the Web interface

⚠ CAUTION:

- You cannot log out by directly closing the browser.
- For security purposes, log out of the Web interface after you finish your operations.

To log out of the Web interface:

1. Save the current configuration.

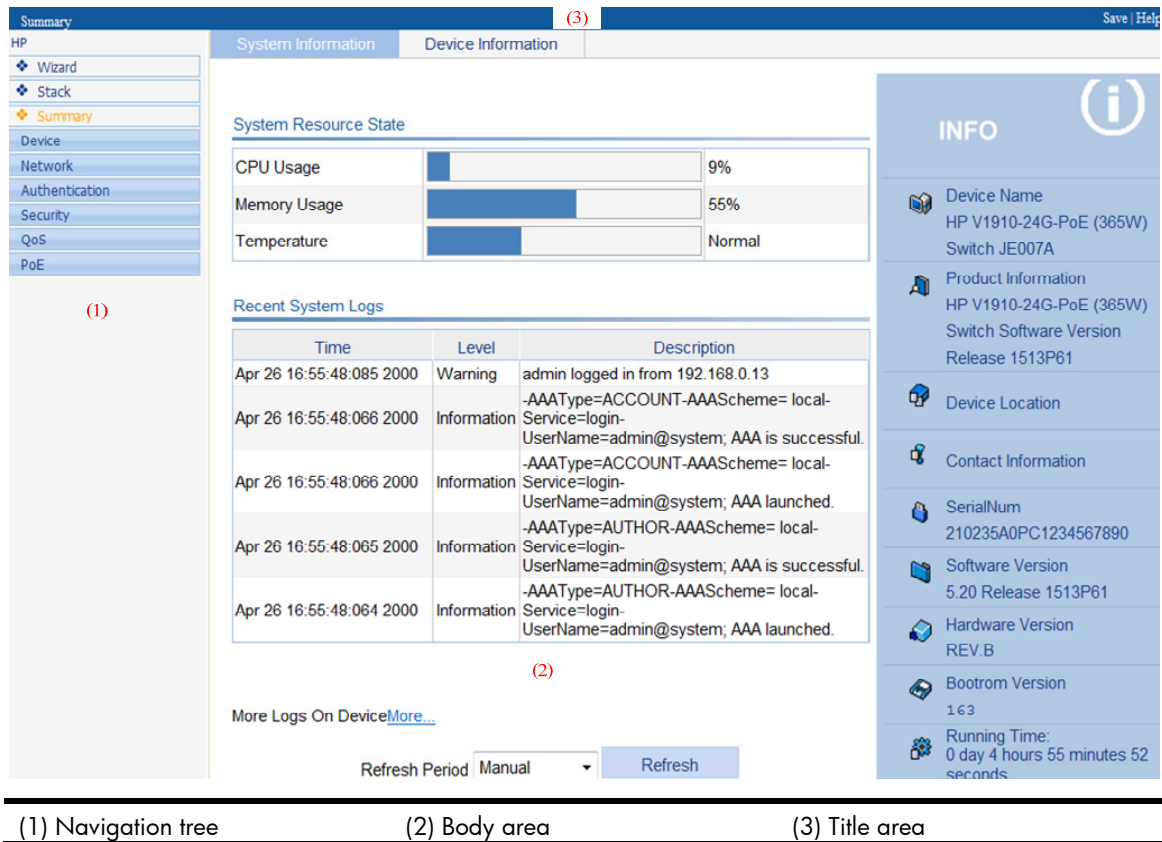

Because the system does not save the current configuration automatically, HP recommends that you perform this step to avoid loss of configuration.

2. Click **Logout** in the upper-right corner of the Web interface, as shown in Figure 9.

Web interface

The Web interface includes these parts: navigation area, title area, and body area.

Figure 9 Web-based configuration interface

- **Navigation area**—Organizes the Web-based NM function menus in the form of a navigation tree, where you can select function menus as needed. The result is displayed in the body area.
- **Body area**—The area where you can configure and display a function.
- **Title area**—On the left, displays the path of the current configuration interface in the navigation area; on the right, provides the **Save** button to quickly save the current configuration, the **Help** button to display the Web-related help information, and the **Logout** button to log out of the Web interface.

Web user level

Web user levels, ranging from low to high, are **visitor**, **monitor**, **configure**, and **management**. A user with a higher level has all the operating rights of a user with a lower level.

- **Visitor**—Users of this level can only use the network diagnostic tools **ping** and **Trace Route**. They can neither access the device data nor configure the device.
- **Monitor**—Users of this level can only access the device data but cannot configure the device.

- **Configure**—Users of this level can access device data and configure the device, but they cannot upgrade the host software, add/delete/modify users, or backup/restore configuration files.
- **Management**—Users of this level can perform any operations to the device.

Web-based NM functions

User level in [Table 1](#) indicates that users of this level or users of a higher level can perform the corresponding operations.

Table 1 Web-based NM function description

Function menu		Description	User level	
Wizard	IP Setup	Perform quick configuration of the device.	Management	
Stack	Setup	Display global settings and port settings of a stack.	Configure	
		Configure global parameters and stack ports.	Management	
	Topology Summary	Display the topology summary of a stack.	Configure	
	Device Summary	Display the control panels of stack members.	Configure	
Summary	System Information	Display the basic system information, system resource state, and recent system operation logs.	Monitor	
	Device Information	Display the port information about the device.	Monitor	
Device	Basic	System Name	Display and configure the system name.	Configure
		Web Idle Timeout	Display and configure the idle timeout period for logged-in users.	Configure
	Device Maintenance	Software Upgrade	Upload upgrade file from local host, and upgrade the system software.	Management
		Reboot	Reboot the device.	Management
		Electronic Label	Display the electronic label of the device.	Monitor
		Diagnostic Information	Generate diagnostic information file and view or save the file to local host.	Management
	System Time	System Time	Display and configure the system date and time.	Configure
		Net Time	Display the synchronization status of the system clock and configure the network time.	Monitor
	Syslog	Loglist	Display and refresh system logs.	Monitor
			Clear system logs.	Configure
		Loghost	Display and configure the loghost.	Configure
		Log Setup	Display and configure the buffer capacity and interval for refreshing system logs.	Configure
	Configuration	Backup	Back up the configuration file to be used at the next startup from the device to the host of the current user.	Management

Function menu		Description	User level
	Restore	Upload the configuration file to be used at the next startup from the host of the current user to the device.	Management
	Save	Save the current configuration to the configuration file to be used at the next startup.	Configure
	Initialize	Restore the factory default settings.	Configure
File Management	File Management	Manage files on the device, such as displaying the file list, downloading a file, uploading a file, and removing a file.	Management
Port Management	Summary	Display port information by features.	Monitor
	Detail	Display feature information by ports.	Monitor
	Setup	Create, modify, delete, and enable/disable a port, and clear port statistics.	Configure
Port Mirroring	Summary	Display the configuration information about a port mirroring group.	Monitor
	Create	Create a port mirroring group.	Configure
	Remove	Remove a port mirroring group.	Configure
	Modify Port	Configure ports for a mirroring group.	Configure
Users	Summary	Display the brief information about FTP and Telnet users.	Monitor
	Super Password	Configure a password for a lower-level user to switch from the current access level to the management level.	Management
	Create	Create an FTP or Telnet user.	Management
	Modify	Modify FTP or Telnet user information.	Management
	Remove	Remove an FTP or a Telnet user.	Management
	Switch To Management	Switch the current user level to the management level.	Visitor
Loopback	Loopback	Perform loopback tests on Ethernet interfaces.	Configure
VCT	VCT	Check the status of the cables connected to Ethernet ports.	Configure
Flow Interval	Port Traffic Statistics	Display the average rate at which the interface receives and sends packets within a specified time interval.	Monitor
	Interval Configuration	Set an interval for collecting traffic statistics on interfaces.	Configure
Storm Constrain	Storm Constrain	Display and set the interval for collecting storm constrain statistics. Display, create, modify, and remove the port traffic threshold.	Configure
RMON	Statistics	Display, create, modify, and clear RMON statistics.	Configure

Function menu			Description	User level
	History	Display, create, modify, and clear RMON history sampling information.		Configure
	Alarm	Display, create, modify, and clear alarm entries.		Configure
	Event	Display, create, modify, and clear event entries.		Configure
	Log	Display log information about RMON events.		Configure
Energy Saving	Energy Saving	Display and configure the energy saving settings of an interface.		Configure
SNMP	Setup	Display and refresh SNMP configuration and statistics information.		Monitor
		Configure SNMP.		Configure
	Community	Display SNMP community information.		Monitor
		Create, modify, and delete an SNMP community.		Configure
	Group	Display SNMP group information.		Monitor
		Create, modify, and delete an SNMP group.		Configure
	User	Display SNMP user information.		Monitor
		Create, modify, and delete an SNMP user.		Configure
	Trap	Display the status of the SNMP trap function and information about target hosts.		Monitor
		Enable or disable the SNMP trap function; create, modify, and delete a target host.		Configure
	View	Display SNMP view information.		Monitor
		Create, modify, and delete an SNMP view.		Configure
Interface Statistics	Interface Statistics	Display and clear the statistics information about an interface.		Configure
Net	VLAN	Select VLAN	Select a VLAN range.	Monitor

Function menu		Description	User level
	Create	Create VLANs.	Configure
	Port Detail	Display the VLAN-related details of a port.	Monitor
	Detail	Display the member port information about a VLAN.	Monitor
	Modify VLAN	Modify the description and member ports of a VLAN.	Configure
	Modify Port	Change the VLAN to which a port belongs.	Configure
	Remove	Remove VLANs.	Configure
VLAN Interface	Summary	Display information about VLAN interfaces by address type.	Monitor
	Create	Create VLAN interfaces and configure IP addresses for them.	Configure
	Modify	Modify the IP addresses and status of VLAN interfaces.	Configure
	Remove	Remove VLAN interfaces.	Configure
Voice VLAN	Summary	Display voice VLAN information globally or on a port.	Monitor
	Setup	Configure the global voice VLAN.	Configure
	Port Setup	Configure a voice VLAN on a port.	Configure
	OUI Summary	Display the addresses of the OUIs that can be identified by voice VLAN.	Monitor
	OUI Add	Add the address of an OUI that can be identified by voice VLAN.	Configure
	OUI Remove	Remove the address of an OUI that can be identified by voice VLAN.	Configure
MAC	MAC	Display MAC address information.	Monitor
		Create and remove MAC addresses.	Configure
	Setup	Display and configure MAC address aging time.	Configure
MSTP	Region	Display information about MST regions.	Monitor
		Modify MST regions.	Configure
	Global	Set global MSTP parameters.	Configure
	Port Summary	Display the MSTP information about ports.	Monitor
	Port Setup	Set MSTP parameters on ports.	Configure
Link Aggregation	Summary	Display information about link aggregation groups.	Monitor
	Create	Create link aggregation groups.	Configure
	Modify	Modify link aggregation groups.	Configure
	Remove	Remove link aggregation groups.	Configure

Function menu		Description	User level
LACP	Summary	Display information about LACP-enabled ports and their partner ports.	Monitor
	Setup	Set LACP priorities.	Configure
LLDP	Port Setup	Display the LLDP configuration information, local information, neighbor information, statistics information, and status information about a port.	Monitor
		Modify LLDP configuration on a port.	Configure
	Global Setup	Display global LLDP configuration information.	Monitor
		Configure global LLDP parameters.	Configure
	Global Summary	Display global LLDP local information and statistics.	Monitor
	Neighbor Summary	Display global LLDP neighbor information.	Monitor
ARP Management	ARP Table	Display ARP table information.	Monitor
		Add, modify, and remove ARP entries.	Configure
	Gratuitous ARP	Display the configuration information about gratuitous ARP.	Monitor
		Configure gratuitous ARP.	Configure
ARP Anti-Attack	ARP Detection	Display ARP detection configuration information.	Monitor
		Configure ARP detection.	Configure
IGMP Snooping	Basic	Display global IGMP snooping configuration information or the IGMP snooping configuration information in a VLAN, and the IGMP snooping multicast entry information.	Monitor
		Configure IGMP snooping globally or in a VLAN.	Configure
	Advanced	Display the IGMP snooping configuration information on a port.	Monitor
		Configure IGMP snooping on a port.	Configure
MLD Snooping	Basic	Display global MLD snooping configuration information or the MLD snooping configuration information in a VLAN, and the MLD snooping multicast entry information.	Monitor
		Configure MLD snooping globally or in a VLAN.	Configure
	Advanced	Display the MLD snooping configuration information on a port.	Monitor
		Configure MLD snooping on a port.	Configure
IPv4 Routing	Summary	Display the IPv4 active route table.	Monitor
	Create	Create an IPv4 static route.	Configure
	Remove	Delete the selected IPv4 static routes.	Configure
IPv6 Routing	Summary	Display the IPv6 active route table.	Monitor
	Create	Create an IPv6 static route.	Configure

Function menu		Description	User level	
IPv6 Management	Remove	Delete the selected IPv6 static routes.	Configure	
	IPv6 Service	Enable or disable IPv6 service.	Configure	
	DHCP	DHCP Relay	Display information about the DHCP status, advanced configuration information about the DHCP relay agent, DHCP server group configuration, DHCP relay agent interface configuration, and the DHCP client information.	Monitor
			Enable/disable DHCP, configure advanced DHCP relay agent settings, configure a DHCP server group, and enable/disable the DHCP relay agent on an interface.	Configure
		DHCP Snooping	Display the status, trusted and untrusted ports and DHCP client information about DHCP snooping.	Monitor
			Enable/disable DHCP snooping, and configure DHCP snooping trusted and untrusted ports.	Configure
	Service	Service	Display the states of services: enabled or disabled.	Configure
			Enable/disable services, and set related parameters.	Management
	Diagnostic Tools	IPv4 Ping	Ping an IPv4 address.	Visitor
		IPv6 Ping	Ping an IPv6 address.	Visitor
IPv4 Traceroute		Perform IPv4 trace route operations.	Visitor	
IPv6 Traceroute		Perform IPv6 trace route operations.	Visitor	
ARP Management	ARP Table	Display ARP table information.	Monitor	
		Add, modify, and remove ARP entries.	Configure	
	Gratuitous ARP	Display the configuration information about gratuitous ARP.	Monitor	
		Configure gratuitous ARP.	Configure	
ARP Anti-Attack	ARP Detection	Display ARP detection configuration information.	Monitor	
		Configure ARP detection.	Configure	
Authentication	802.1X	802.1X	Display 802.1X configuration information globally or on a port.	Monitor
			Configure 802.1X globally or on a port.	Configure
	Portal	Portal Server	Display configuration information about the portal server and advanced parameters for portal authentication.	Monitor
			Add and delete a portal server, and modify advanced parameters for portal authentication.	Configure

Function menu		Description	User level	
AAA	Free Rule	Display the portal-free rule configuration information.	Monitor	
		Add and delete a portal-free rule.	Configure	
	Domain Setup	Display ISP domain configuration information.	Monitor	
		Add and remove ISP domains.	Management	
	Authentication	Display the authentication configuration information about an ISP domain.	Monitor	
		Specify authentication methods for an ISP domain.	Management	
	Authorization	Display the authorization method configuration information about an ISP domain.	Monitor	
		Specify authorization methods for an ISP domain.	Management	
	Accounting	Display the accounting method configuration information about an ISP domain.	Monitor	
		Specify accounting methods for an ISP domain.	Management	
	RADIUS	RADIUS Server	Display and configure RADIUS server information.	Management
		RADIUS Setup	Display and configure RADIUS parameters.	Management
	Users	Local User	Display configuration information about local users.	Monitor
			Create, modify, and remove a local user.	Management
		User Group	Display configuration information about user groups.	Monitor
			Create, modify, and remove a user group.	Management
PKI	Entity	Display information about PKI entities.	Monitor	
		Add, modify, and delete a PKI entity.	Configure	
	Domain	Display information about PKI domains.	Monitor	
		Add, modify, and delete a PKI domain.	Configure	
	Certificate	Display the certificate information about PKI domains and the contents of a certificate.	Monitor	
		Generate a key pair, destroy a key pair, retrieve a certificate, request a certificate, and delete a certificate.	Configure	
	CRL	Display the contents of the CRL.	Monitor	
		Receive the CRL of a domain.	Configure	
Security	Port Isolate Group	Summary	Display port isolation group information.	Monitor
		Port Setup	Configure the ports in an isolation group.	Configure
	Authorized IP	Summary	Display the configurations of authorized IP, the associated IPv4 ACL list, and the associated IPv6 ACL list.	Management
		Setup	Configure authorized IP.	Management

Function menu		Description	User level	
QoS	Time Range	Summary	Display time range configuration information.	Monitor
		Create	Create a time range.	Configure
		Remove	Delete a time range.	Configure
	ACL IPv4	Summary	Display IPv4 ACL configuration information.	Monitor
		Create	Create an IPv4 ACL.	Configure
		Basic Setup	Configure a rule for a basic IPv4 ACL.	Configure
		Advanced Setup	Configure a rule for an advanced IPv4 ACL.	Configure
		Link Setup	Create a rule for a link layer ACL.	Configure
		Remove	Delete an IPv4 ACL or its rules.	Configure
	ACL IPv6	Summary	Display IPv6 ACL configuration information.	Monitor
		Create	Create an IPv6 ACL.	Configure
		Basic Setup	Configure a rule for a basic IPv6 ACL.	Configure
		Advanced Setup	Configure a rule for an advanced IPv6 ACL.	Configure
		Remove	Delete an IPv6 ACL or its rules.	Configure
	Queue	Summary	Display the queue information about a port.	Monitor
		Setup	Configure a queue on a port.	Configure
	Line Rate	Summary	Display line rate configuration information.	Monitor
		Setup	Configure the line rate.	Configure
	Classifier	Summary	Display classifier configuration information.	Monitor
		Create	Create a class.	Configure
		Setup	Configure the classification rules for a class.	Configure
		Remove	Delete a class or its classification rules.	Configure
	Behavior	Summary	Display traffic behavior configuration information.	Monitor
		Create	Create a traffic behavior.	Configure
		Setup	Configure actions for a traffic behavior.	Configure
		Port Setup	Configure traffic mirroring and traffic redirecting for a traffic behavior	Configure
		Remove	Delete a traffic behavior.	Configure
	QoS Policy	Summary	Display QoS policy configuration information.	Monitor
		Create	Create a QoS policy.	Configure
		Setup	Configure the classifier-behavior associations for a QoS policy.	Configure
		Remove	Delete a QoS policy or its classifier-behavior associations.	Configure
	Port Policy	Summary	Display the QoS policy applied to a port.	Monitor

Function menu		Description	User level
	Setup	Apply a QoS policy to a port.	Configure
	Remove	Remove the QoS policy from the port.	Configure
	Priority Mapping	Display priority mapping table information.	Monitor
		Modify the priority mapping entries.	Configure
	Port Priority	Display port priority and trust mode information.	Monitor
		Modify port priority and trust mode.	Configure
PoE PoE	Summary	Display PSE information and PoE interface information.	Monitor
	PSE Setup	Configure a PoE interface.	Configure
	Port Setup	Configure a port.	Configure

Common items on the Web pages

Buttons and icons

Table 2 Commonly used buttons and icons

Button and icon	Function
	Applies the configuration on the current page.
	Cancels the configuration on the current page, and returns to the corresponding list page or the Device Info page.
	Refreshes the current page.
	Clears all entries in a list or all statistics.
	Adds an item.
 	Removes the selected items.
	Selects all the entries in a list, or selects all ports on the device panel.
	Clears all the entries in a list, or clears all ports on the device panel.
	Buffers settings you made and proceeds to the next step without applying the settings. This button is typically present on the configuration wizard.
	Buffers settings you made and returns to the previous step without applying the settings. This button is typically present on the configuration wizard.
	Applies all settings you made at each step and finishes the configuration task. This button is typically present on the configuration wizard.

Button and icon	Function
	Accesses a configuration page to modify settings. This icon is typically present in the Operation column in a list.
	Deletes an entry. This icon is typically present in the Operation column in a list.

Page display

The Web interface can display contents by pages, as shown in Figure 10. You can set the number of entries displayed per page, and view the contents on the first, previous, next, and last pages, or go to any page that you want to check.

Search function

The Web interface provides you with the basic and advanced searching functions to display only the entries that match specific searching criteria.

- **Basic search**—As shown in Figure 10, input the keyword in the text box above the list, select a search item from the list and click **Search** to display the entries that match the criteria. Figure 11 shows an example of searching for entries with VLAN ID 2.

Figure 11 Basic search function example

<input type="text" value="2"/>	VLAN ID	Search	Advanced Search			
<input type="checkbox"/>	IP Address	MAC Address	VLAN ID	Port	Type	Operation
<input type="checkbox"/>	2.2.2.1	00e0-dc28-a411	2	GigabitEthernet1/0/2	Static	 
<input type="checkbox"/>	2.2.2.10	00e0-dc28-a4e1	2	GigabitEthernet1/0/3	Static	 

- **Advanced search**—As shown in Figure 10, you can click the **Advanced Search** link to open the advanced search page, as shown in Figure 12. Specify the search criteria, and click **Apply** to display the entries that match the criteria.

Take the ARP table shown in Figure 10 as an example. If you want to search for the ARP entries with interface being GigabitEthernet1/0/19, and IP address range being 192.168.1.50 to 192.168.1.59, follow these steps:

1. Click the **Advanced Search** link, specify the search criteria on the advanced search page as shown in Figure 13, and click **Apply**. The ARP entries with interface being GigabitEthernet1/0/19 are displayed.

Figure 13 Advanced search function example (I)

Sort function

The Web interface provides you with the basic functions to display entries in certain orders.

On a list page, you can click the blue heading item of each column to sort the entries based on the heading item you selected. After your clicking, the heading item is displayed with an arrow beside it as shown in [Figure 16](#). The upward arrow indicates the ascending order, and the downward arrow indicates the descending order.

Configuring the switch at the CLI

The HP 1910 Switch Series can be configured through the CLI, Web interface, and SNMP/MIB. The Web interface supports all 1910 Switch Series configurations. These configuration methods are suitable for different application scenarios. The CLI provides configuration commands to facilitate your operation, which are described in this chapter. To perform configurations not supported by the CLI, use the Web interface.

You will enter user view directly after you log in to the device. Commands in the document are all performed in user view.

Getting started with the CLI

The CLI provides configuration commands to facilitate your operation. For example, if you forget the IP address of VLAN-interface 1 and cannot log in to the device through the Web interface, you can connect the console port of the device to a PC, and reconfigure the IP address of VLAN-interface 1 at the CLI.

Setting up the configuration environment

⚠ CAUTION:

Identify the mark on the console port to make sure you are connecting to the correct port.

To set up the configuration environment, connect a terminal (a PC in this example) to the console port on the switch with a console cable.

A console cable is an 8-core shielded cable, with a crimped RJ-45 connector at one end for connecting to the console port of the switch, and a DB-9 female connector at the other end for connecting to the serial port on the console terminal.

Figure 17 Console cable

Use a console cable to connect a terminal device to the switch, as follows:

1. Plug the DB-9 female connector to the serial port of the console terminal or PC.
2. Connect the RJ-45 connector to the console port of the switch.

NOTE:

- The serial port on a PC does not support hot swapping. When you connect a PC to a powered-on switch, connect the DB-9 connector of the console cable to the PC before connecting the RJ-45 connector to the switch.
 - When you disconnect a PC from a powered-on switch, disconnect the DB-9 connector of the console cable from the PC after disconnecting the RJ-45 connector from the switch.
-

Setting terminal parameters

To configure and manage the switch, you must run a terminal emulator program on the console terminal.

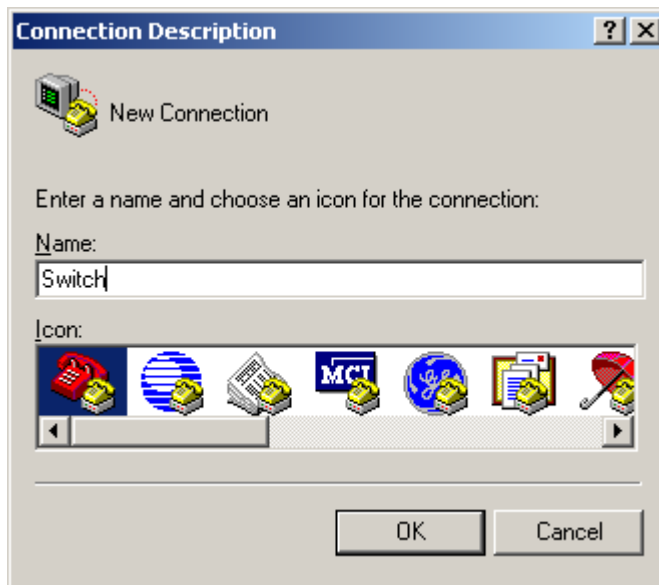

The following are the required terminal settings:

- **Bits per second**—38,400
- **Data bits**—8
- **Parity**—None
- **Stop bits**—1
- **Flow control**—None
- **Emulation**—VT100

To set terminal parameters, for example, on a Windows XP HyperTerminal:

1. Select **Start > All Programs > Accessories > Communications > HyperTerminal**.
The **Connection Description** dialog box appears.
2. Enter the name of the new connection in the **Name** field and click **OK**.

Figure 18 Connection description

3. Select the serial port to be used from the **Connect using** list, and click **OK**.

Figure 19 Setting the serial port used by the HyperTerminal connection

4. Set **Bits per second** to **38400**, **Data bits** to **8**, **Parity** to **None**, **Stop bits** to **1**, and **Flow control** to **None**, and click **OK**.

Figure 20 Setting the serial port parameters

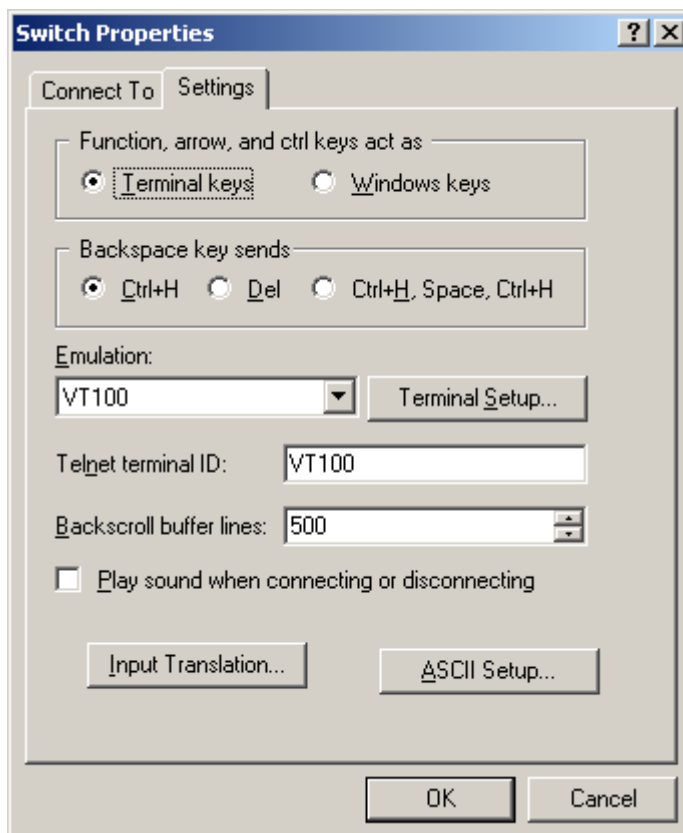

5. Select **File > Properties** in the HyperTerminal window.

Figure 21 HyperTerminal window

6. Click the **Settings** tab, set the emulation to **VT100**, and click **OK** in the **Switch Properties** dialog box.

Figure 22 Setting terminal emulation in Switch Properties dialog box

Logging in to the CLI

The login process requires a username and password. The default username for first time configuration is **admin**, no password is required. Usernames and passwords are case sensitive.

To log in to the CLI:

1. Press **Enter**. The **Username** prompt displays:

```
Login authentication
```

```
Username:
```

2. Enter your username at the **Username** prompt.

```
Username:admin
```

3. Press **Enter**. The **Password** prompt appears.

```
Password:
```

The login information is verified, and the following CLI menu appears:

```
<HP 1910 Switch>
```

If the password is invalid, the following message appears and process restarts.

```
% Login failed!
```

CLI commands

This section contains the following commands:

Task	Command
Display a list of CLI commands on the device.	?
Reboot the device and run the default configuration.	initialize
Configure VLAN-interface 1 to obtain an IPv4 address through DHCP or manual configuration.	ipsetup { dhcp ip-address ip-address { mask mask-length } [default-gateway ip-address] }
Configure VLAN-interface 1 to obtain an IPv6 address through the autoconfiguration function or manual configuration.	ipsetup ipv6 { auto address { ipv6-address prefix-length ipv6-address/prefix-length } [default-gateway ipv6-address] }
Modify the login password.	password
Log out of the system.	quit
Download the Boot ROM image or system software image file from the TFTP server and specify it as the startup configuration file.	upgrade [ipv6] server-address source-filename { bootrom runtime }
Reboot the device and run the main configuration file.	reboot
View the summary information about the device.	summary
Ping a specified destination.	ping [ipv6] host
Tear down the current connection and quit the system.	quit
Establish a Telnet connection.	telnet remote-host [service-port] [source { interface interface-type interface-number ip ip-address }]

initialize

Syntax

initialize

Parameters

None

Description

Use **initialize** to delete the configuration file to be used at the next startup and reboot the device with the default configuration being used during reboot.

Use the command with caution because this command deletes the configuration file to be used at the next startup and restores the factory default settings.

Examples

```
# Delete the configuration file to be used at the next startup and reboot the device with the default configuration being used during reboot.
```

```
<Sysname> initialize
```

```
The startup configuration file will be deleted and the system will be rebooted.Continue?  
[Y/N]:y
```

```
Please wait...
```

ipsetup

Syntax

ipsetup { dhcp | ip-address ip-address { mask | mask-length } [default-gateway ip-address] }

Parameters

dhcp: Enables VLAN-interface 1 to obtain an IPv4 address through DHCP.

ip-address ip-address: Specifies an IPv4 address for VLAN-interface 1 in dotted decimal notation.

mask: Subnet mask in dotted decimal notation.

mask-length: Subnet mask length, the number of consecutive ones in the mask, in the range of 0 to 32.

default-gateway ip-address: Specifies the IPv4 address of the default gateway. If you specify this option, the command not only assigns an IPv4 address to the interface, but also specifies a default route for the device.

Description

Use **ipsetup dhcp** to specify VLAN-interface 1 to obtain an IPv4 address through DHCP.

Use **ipsetup ip address ip-address { mask | mask-length }** to assign an IPv4 address to VLAN-interface 1.

By default, the device automatically obtains its IP address through DHCP. If the device cannot obtain an IP address through DHCP, it uses the assigned default IP address. For more information, see [Figure 5](#).

If there is no VLAN-interface 1, either command creates VLAN-interface 1 first, and then specifies its IP address.

Examples

```
# Create VLAN-interface 1 and specify the interface to obtain an IPv4 address through DHCP.
```

```
<Sysname> ipsetup dhcp
```

Create VLAN-interface 1 and assign 192.168.1.2 to the interface, and specify 192.168.1.1 as the default gateway.

```
<Sysname> ipsetup ip-address 192.168.1.2 24 default-gateway 192.168.1.1
```

ipsetup ipv6

Syntax

```
ipsetup ipv6 { auto | address { ipv6-address prefix-length | ipv6-address/prefix-length }  
[ default-gateway ipv6-address ] }
```

Parameters

auto: Enables the stateless address autoconfiguration function. VLAN-interface 1 can automatically generate a global unicast address and link local address.

address: Enables manual configuration of a global unicast IPv6 address for VLAN-interface 1.

ipv6-address: Specifies an IPv6 address.

prefix-length: Prefix length in the range of 1 to 128.

default-gateway *ipv6-address*: Specifies the IPv6 address of the default gateway. If you specify this option, the command not only assigns an IPv6 address to the interface, but also specifies a default route for the device.

Description

Use **ipsetup ipv6 auto** to enable the stateless address autoconfiguration function so a global unicast address and link local address can be automatically generated.

Use **ipsetup ipv6 address** { *ipv6-address prefix-length* | *ipv6-address/prefix-length* } [**default-gateway** *ipv6-address*] to manually assign an IPv6 address to VLAN-interface 1.

Examples

Create VLAN-interface 1 and enable VLAN-interface 1 to automatically generate a global unicast IPv6 address and link local address.

```
<Sysname> ipsetup ipv6 auto
```

Create VLAN-interface 1 and assign 2001::2 to the interface, with the prefix length 64, and specify 2001::1 as the default gateway.

```
<Sysname> ipsetup ipv6 address 2001::2 64 default-gateway 2001::1
```

password

Syntax

```
password
```

Parameters

None

Description

Use **password** to modify the login password of a user.

Examples

Modify the login password of user admin.

```
<Sysname> password
```

```
Change password for user: admin
Old password: ***
Enter new password: **
Retype password: **
The password has been successfully changed.
```

ping

Syntax

ping *host*

Parameters

host: Specifies a destination IPv4 address (in dotted decimal notation) or host name (a string of 1 to 255 characters).

Description

Use **ping** to ping a specified destination.

To terminate a ping operation, press **Ctrl+C**.

Examples

Ping IP address 1.1.2.2.

```
<Sysname> ping 1.1.2.2
PING 1.1.2.2: 56 data bytes, press CTRL_C to break
  Reply from 1.1.2.2: bytes=56 Sequence=1 ttl=254 time=205 ms
  Reply from 1.1.2.2: bytes=56 Sequence=2 ttl=254 time=1 ms
  Reply from 1.1.2.2: bytes=56 Sequence=3 ttl=254 time=1 ms
  Reply from 1.1.2.2: bytes=56 Sequence=4 ttl=254 time=1 ms
  Reply from 1.1.2.2: bytes=56 Sequence=5 ttl=254 time=1 ms

--- 1.1.2.2 ping statistics ---
  5 packet(s) transmitted
  5 packet(s) received
  0.00% packet loss
  round-trip min/avg/max = 1/41/205 ms
```

The output shows that IP address 1.1.2.2 is reachable and the echo replies are all returned from the destination. The minimum, average, and maximum roundtrip intervals are 1 millisecond, 41 milliseconds, and 205 milliseconds respectively.

ping ipv6

Syntax

ping ipv6 *host*

Parameters

host: Specifies a destination IPv6 address or host name, a string of 1 to 255 characters.

Description

Use **ping ipv6** to ping a specified destination.

To terminate a ping operation, press **Ctrl+C**.

Examples

```
# Ping IPv6 address 2001::4.
<Sysname> ping ipv6 2001::4
PING 2001::4 : 56 data bytes, press CTRL_C to break
  Reply from 2001::4
    bytes=56 Sequence=1 hop limit=64 time = 15 ms
  Reply from 2001::4
    bytes=56 Sequence=2 hop limit=64 time = 2 ms
  Reply from 2001::4
    bytes=56 Sequence=3 hop limit=64 time = 11 ms
  Reply from 2001::4
    bytes=56 Sequence=4 hop limit=64 time = 2 ms
  Reply from 2001::4
    bytes=56 Sequence=5 hop limit=64 time = 12 ms

--- 2001::4 ping statistics ---
  5 packet(s) transmitted
  5 packet(s) received
  0.00% packet loss
  round-trip min/avg/max = 2/8/15 ms
```

The output shows that IPv6 address 2001::4 is reachable and the echo replies are all returned from the destination. The minimum, average, and maximum roundtrip intervals are 2 milliseconds, 8 milliseconds, and 15 milliseconds respectively.

quit

Syntax

quit

Parameters

None

Description

Use **quit** to log out of the system.

Examples

```
# Log out of the system.
<Sysname> quit
*****
* Copyright (c) 2004-2012 Hewlett-Packard Development Company, L.P.      *
* Without the owner's prior written consent,                             *
* no decompiling or reverse-engineering shall be allowed.                *
*****
<Sysname>
```

reboot

Syntax

reboot

Parameters

None

Description

Use **reboot** to reboot the device and run the main configuration file.

Use the command with caution because reboot results in service interruption.

If the main configuration file is corrupted or does not exist, the device cannot be rebooted with the **reboot** command. You can specify a new main configuration file to reboot the device, or you can power off the device, and then power it on, and the system will automatically use the backup configuration file at the next startup.

If you reboot the device when file operations are being performed, the system does not execute the command to ensure security.

Examples

If the configuration does not change, reboot the device.

```
<Sysname> reboot
Start to check configuration with next startup configuration file, please
wait.....DONE!
This command will reboot the device. Continue? [Y/N]:y
Now rebooting, please wait...
```

If the configuration changes, reboot the device.

```
<Sysname> reboot
Start to check configuration with next startup configuration file, please
wait.....DONE!
This command will reboot the device. Current configuration will be lost in next startup
if you continue. Continue? [Y/N]:y
Now rebooting, please wait...
```

summary

Syntax

summary

Parameters

None

Description

Use **summary** to view the summary of the device, including the IP address of VLAN-interface 1, and software version information.

Examples

Display summary information about the device.

```
<sysname>summary
Select menu option: Summary
```

```

IP Method:                               Manual

telnet

Syntax

telnet *remote-host* [*service-port*] [**source** { **interface** *interface-type interface-number* | **ip** *ip-address* }]

Parameters

remote-host: IPv4 address or host name of a remote host, a case insensitive string of 1 to 20 characters.

service-port: TCP port number of the Telnet service on the remote host. It is in the range of 0 to 65535. The default is 23.

source: Specifies the source interface or source IPv4 address of Telnet packets.

interface *interface-type interface-number*: Specifies the source interface by its type and number. The source IPv4 address of the Telnet packets that are sent is the IPv4 address of the specified source interface. *interface-type interface-number* represents the interface type and number.

ip *ip-address*: Specifies the source IPv4 address of Telnet packets.

Description

Use **telnet** to telnet to a remote host.

To stop the current Telnet connection, use the **quit** command.

The source IPv4 address or source interface specified by this command is applicable to the current Telnet connection only.

Examples

Telnet to the remote host 1.1.1.2, specifying the source IP address of Telnet packets as 1.1.1.1.

```
<Sysname> telnet 1.1.1.2 source ip 1.1.1.1
```

upgrade

Syntax

upgrade *server-address source-filename* { **bootrom** | **poe** | **runtime** }

Parameters

server-address: Specifies a TFTP server by its IPv4 address or host name, a string of 1 to 20 characters.

source-filename: Software package name on the TFTP server.

bootrom: Specifies the Boot ROM image to be upgraded.

poe: Specifies the PoE software to be upgraded.

runtime: Specifies the system software image to be upgraded.

Description

Use **upgrade** *server-address source-filename* **bootrom** to upgrade the Boot ROM image. If the Boot ROM image in the downloaded software package file is not applicable, the original Boot ROM image is used.

Use **upgrade** *server-address source-filename* **poe** to upgrade the PoE software.

Use **upgrade** *server-address source-filename* **runtime** to upgrade the system software image file. If the system software image file in the downloaded software package file is not applicable, the original system software image file is used.

To validate the downloaded software package file, reboot the device.

NOTE:

The HP 1910 Switch Series does not provide an independent Boot ROM image. It integrates the Boot ROM image with the system software image file together in a software package file with the extension name of **.bin**.

Examples

Download software package file **main.bin** from the TFTP server to upgrade the Boot ROM image.

```
<Sysname> upgrade 192.168.20.41 main.bin bootrom
```

Download software package file **poe.bin** from the TFTP server to upgrade the PoE software.

```
<Sysname> upgrade 192.168.20.41 poe.bin poe
```

Download software package file **main.bin** from the TFTP server to upgrade the system software image.

```
<Sysname> upgrade 192.168.20.41 main.bin runtime
```

upgrade ipv6

Syntax

upgrade ipv6 *server-address source-filename* { **bootrom** | **poe** | **runtime** }

Parameters

server-address: Specifies a TFTP server by its IPv6 address.

source-filename: Software package name on the TFTP server.

bootrom: Specifies the Boot ROM image to be upgraded.

poe: Specifies the PoE software to be upgraded.

runtime: Specifies the system software image to be upgraded.

Description

Use **upgrade ipv6** *server-address source-filename* **bootrom** to upgrade the Boot ROM image. If the Boot ROM image in the downloaded software package file is not applicable, the original Boot ROM image is used.

Use **upgrade** *server-address source-filename* **poe** to upgrade the PoE software.

Use **upgrade ipv6** *server-address source-filename* **runtime** to upgrade the system software image file. If the system software image file in the downloaded software package file is not applicable, the original system software image file is used.

To validate the downloaded software package file, reboot the device.

NOTE:

The HP 1910 Switch Series does not provide an independent Boot ROM image. It integrates the Boot ROM image with the system software image file together in a software package file with the extension name of **.bin**.

Examples

Download software package file **main.bin** from the TFTP server to upgrade the Boot ROM image.

```
<Sysname> upgrade ipv6 2001::2 main.bin bootrom
```

Download software package file **poe.bin** from the TFTP server to upgrade the PoE software.

```
<Sysname> upgrade ipv6 2001::2 poe.bin poe
```

Download software package file **main.bin** from the TFTP server to upgrade the system software image.

```
<Sysname> upgrade ipv6 2001::2 main.bin runtime
```

Configuration example for upgrading the system software image at the CLI

Network requirements

As shown in [Figure 23](#), a 1910 switch is connected to the PC through the console cable, and connected to the gateway through GigabitEthernet 1/0/1. The IP address of the gateway is 192.168.1.1/24, and that of the TFTP server where the system software image (suppose its name is **Switch1910.bin**) is located is 192.168.10.1/24. The gateway and the switch can reach each other.

The administrator upgrades the Boot ROM image and the system software image file of the 1910 switch through the PC and sets the IP address of the switch to 192.168.1.2/24.

Figure 23 Network diagram

Configuration procedure

1. Run the TFTP server program on the TFTP server, and specify the path of the file to be loaded. (Omitted)
2. Configure the switch:

Configure the IP address of VLAN-interface 1 of the switch as 192.168.1.2/24, and specify the default gateway as 192.168.1.1.

```
<Switch> ipsetup ip-address 192.168.1.2 24 default-gateway 192.168.1.1
```

Download the software package file **Switch1910.bin** on the TFTP server to the switch, and upgrade the system software image in the package.

```
<Switch> upgrade 192.168.10.1 Switch1910.bin runtime
```

File will be transferred in binary mode

Downloading file from remote TFTP server, please wait.../

TFTP: 10262144 bytes received in 71 second(s)

File downloaded successfully.

Download the software package file **Switch1910.bin** on the TFTP server to the switch, and upgrade the Boot ROM image.

```
<Switch> upgrade 192.168.10.1 Switch1910.bin bootrom
```

The file flash:/Switch1910.bin exists. Overwrite it? [Y/N]:y

Verifying server file...

Deleting the old file, please wait...

File will be transferred in binary mode

Downloading file from remote TFTP server, please wait.../

TFTP: 10262144 bytes received in 61 second(s)

File downloaded successfully.

BootRom file updating finished!

Reboot the switch.

```
<Switch> reboot
```

After getting the new image file, reboot the switch to validate the upgraded image.

Configuration wizard

Overview

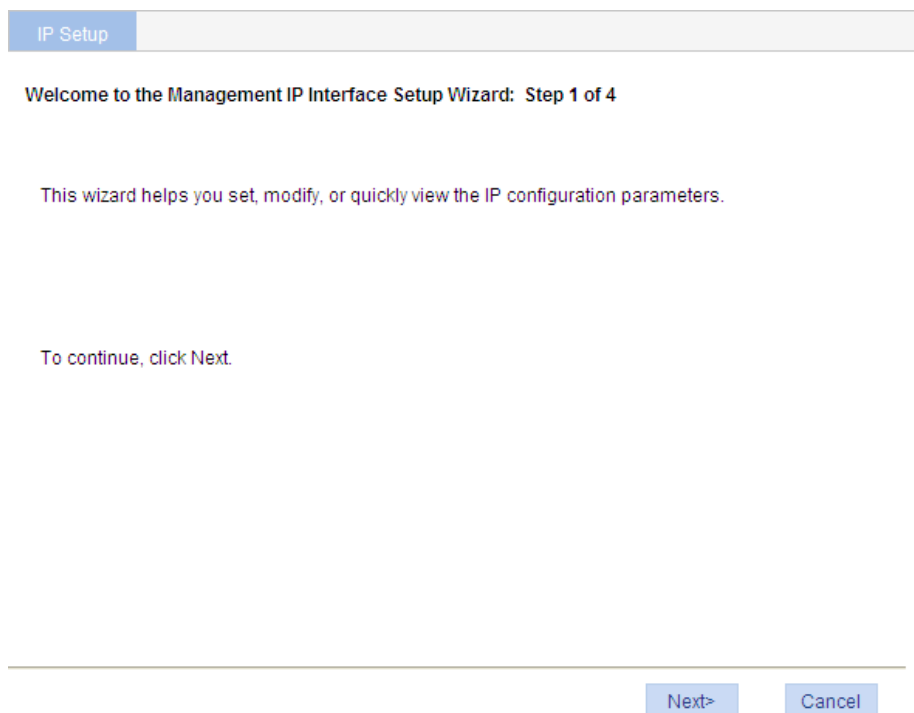

The configuration wizard guides you through configuring the basic service parameters, including the system name, the system location, the contact information, and the management IP address.

Basic service setup

Entering the configuration wizard homepage

Select **Wizard** from the navigation tree.

Figure 24 Configuration wizard homepage

Configuring system parameters

1. On the wizard homepage, click **Next**.

Configuring stack

Overview

The stack management feature enables you to configure and monitor a group of connected switches by logging in to one switch in the stack, as shown in [Figure 28](#).

Figure 28 Network diagram

To set up a stack for a group of connected switches, you must log in to one switch to create the stack. This switch is the master switch for the stack, and you configure and monitor all other member switches on the master switch. The ports that connect the stack member switches are called stack ports.

Configuration task list

Task	Remarks
Configuring the master device of a stack:	
Configuring global stack parameters	Required. Configure a private IP address pool and set up the stack. By default, no IP address pool is configured for a stack and no stack is set up.
Configuring stack ports	Required. Configure the ports connected to member devices as stack ports. By default, no ports are configured as stack ports.
Configuring stack ports	Required. Configure ports connected to the master device or other stack member devices as stack ports. By default, no ports are configured as stack ports.

Task	Remarks
Displaying topology summary of a stack	Optional. Display stack member information.
Displaying device summary of a stack	Optional. Display the control panels of stack members. ⓘ IMPORTANT: To successfully display control panel information, make sure the user account you are logged in with to the master has also been created on each member device. You can configure the user account by selecting Device and then clicking Users from the navigation tree.
Logging in to a member device from the master	Optional. Log in to the web network management interface of a member device from the master device. ⓘ IMPORTANT: To successfully log in to a member device from the master device, make sure the user account you are logged in with to the master has also been created on the member device. You can configure the user account by selecting Device and then clicking Users from the navigation tree.

Configuring global stack parameters

1. Log in to the Web interface of the master device.
2. Select **Stack** from the navigation tree to enter the page shown in [Figure 29](#).
3. Configure global stack parameters in the **Global Settings** area.

Item	Description
Private Net IP	Configure a private IP address pool for the stack.
Mask	<p>The master device automatically picks an IP address from this pool for each member device for intra-stack communication.</p> <p>! IMPORTANT:</p> <p>Make sure the number of IP addresses in the address pool is equal to or greater than the number of devices to be added to the stack. If not, some devices cannot automatically join the stack for lack of private IP addresses.</p>

Item	Description
Build Stack	<p>Create the stack.</p> <p>As the result, the device becomes the master device of the stack and automatically adds the devices connected to its stack ports to the stack.</p> <p>! IMPORTANT:</p> <p>You can delete the stack only on the master device. The Global Settings area is grayed out for stack member devices.</p>

Configuring stack ports

1. Log in to the master device and each member device to perform this task.
2. Select **Stack** from the navigation tree to enter the page shown in [Figure 29](#).
3. Configure stack ports in the **Port Settings** area, as follows:
 - o Select the box before a port name, and click **Enable** to configure the port as a stack port.
 - o Select the box before a port name, and click **Disable** to configure the port as a non-stack port.

Displaying topology summary of a stack

Select **Stack** from the navigation tree and click the **Topology Summary** tab to enter the page shown in [Figure 30](#).

Figure 30 Topology Summary tab

Setup	Topology Summary	Device Summary							
<table><thead><tr><th>Member ID</th><th>Role</th></tr></thead><tbody><tr><td>1</td><td>Slave</td></tr><tr><td>0</td><td>Master</td></tr></tbody></table>		Member ID	Role	1	Slave	0	Master		
Member ID	Role								
1	Slave								
0	Master								

[Table 6](#) describes the fields of topology summary.

Table 6 Field description

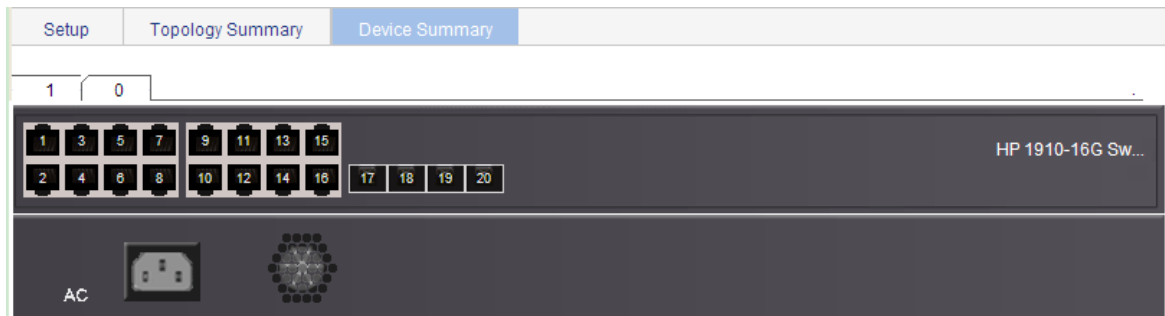

Fields	Description
Device ID	<p>Member ID of the device in the stack:</p> <ul style="list-style-type: none"> • 0—The device is the master device. • Any other value—The device is a member device and the value is the member ID of the member device in the stack.
Device Role	Role of the device in the stack: master or member.

Displaying device summary of a stack

Select **Stack** from the navigation tree and click the **Device Summary** tab to enter the page shown in [Figure 31](#).

View interfaces and power socket layout on the panel of each stack member by clicking their respective tabs.

Figure 31 Device Summary tab (on the master device)

Return to [Configuration task list](#).

Logging in to a member device from the master

1. Select **Stack** from the navigation tree.
2. Click the **Device Summary** tab.
3. Click a member device ID tab.
4. On the page in [Figure 32](#), click the **Configuring the Device** link.

Figure 32 Device Summary tab (on a member device)

Stack configuration example

Network requirements

As shown in [Figure 33](#), create a stack that comprises Switch A, Switch B, Switch C, and Switch D. Use Switch A as the master device so an administrator can log in to any other stack member device through Switch A for remote configuration and management.

Figure 33 Network diagram

Configuration procedure

1. Configure global stack parameters on Switch A:
 - a. Select **Stack** from the navigation tree of Switch A to enter the page of the **Setup** tab, and then perform the following configurations, as shown in [Figure 34](#).
 - b. Type **192.168.1.1** in the field of **Private Net IP**.
 - c. Type **255.255.255.0** in the field of **Mask**.
 - d. Select **Enable** from the **Build Stack** list.
 - e. Click **Apply**.

Member ID		Role	
0		Master	
1		Slave	
2		Slave	
3		Slave	

Configuration guidelines

If a device is already configured as a stack master device, you cannot modify the private IP address pool on the device.

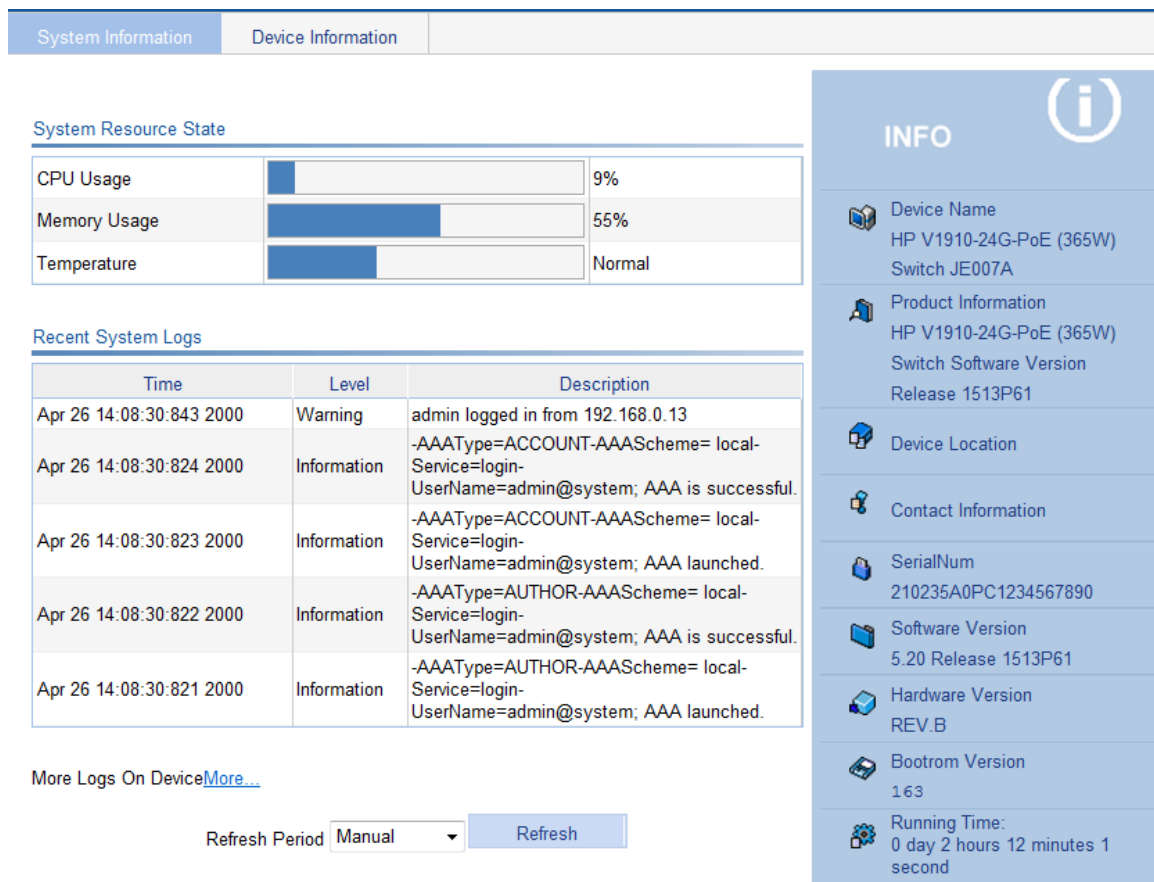

If a device is already configured as a stack member device, the **Global Settings** area on the member device is not available.

Displaying system and device information

Displaying system information

Select Summary from the navigation tree to enter the **System Information** page to view the basic system information, system resource state, and recent system logs.

Figure 39 System information

Displaying basic system information

Table 7 Field description

Item	Description
Device Name	Display the device name.
Product Information	Display the description about the device.
Device Location	Display the device location, which you can configure on the page you enter by selecting Device > SNMP > Setup .

Item	Description
Contact Information	Display the contact information, which you can configure on the page you enter by selecting Device > SNMP > Setup .
SerialNum	Display the serial number of the device.
Software Version	Display the software version of the device.
Hardware Version	Display the hardware version of the device.
Bootrom Version	Display the Boot ROM version of the device.
Running Time	Display the system up time.

Displaying the system resource state

The **System Resource State** area displays the most recent CPU usage, memory usage, and temperature status.

The temperature status is represent by the color of its status bar as follows:

- **Blue**—Normal.
- **Yellow**—Warning.
- **Red**—Alarm.

Displaying recent system logs

Table 8 Field description

Field	Description
Time	Display the time when the system logs were generated.
Level	Display the severity of the system logs.
Description	Display the description of the system logs.

The **System Information** page displays up to five the most recent system logs about the login and logout events.

To display more system logs, click **More** to enter the **Log List** page. You can also enter this page by selecting **Device > Syslog**. For more information, see "[Configuring syslog](#)."

Setting the refresh period

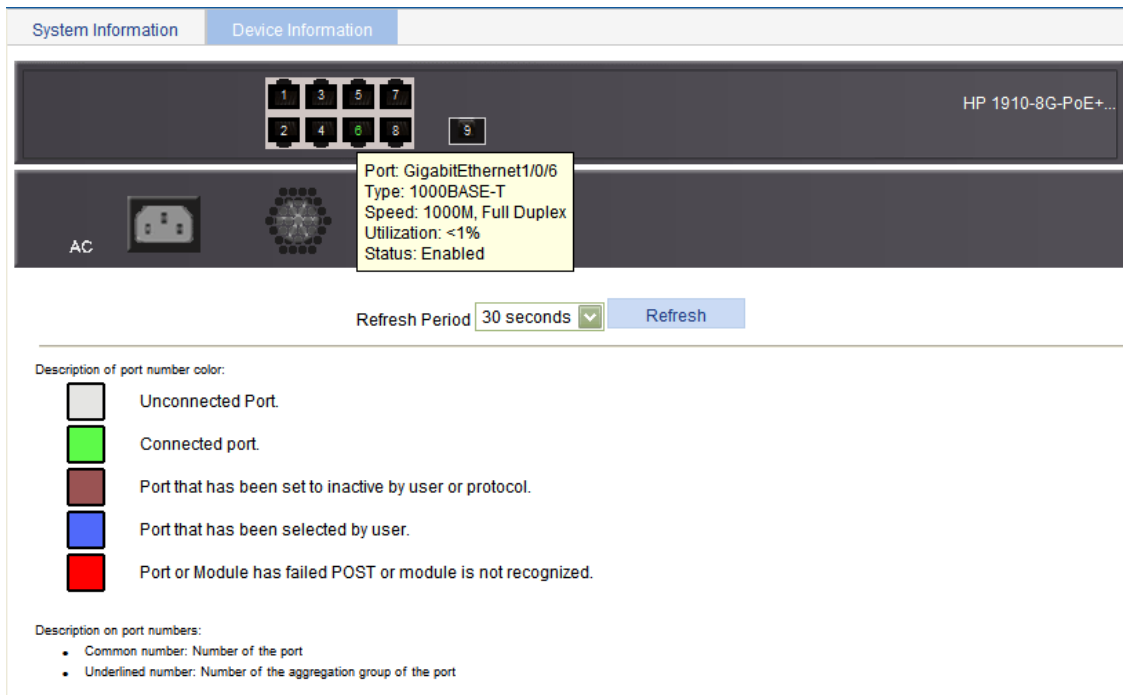

To set the interval for refreshing system information, select one of the following options from the **Refresh Period** list:

- If you select a certain period, the system refreshes system information at the specified interval.
- If you select **Manual**, the system refreshes system information only when you click the **Refresh** button.

Displaying device information

Select **Summary** from the navigation tree, and click the **Device Information** tab to enter the page displaying the device ports, power supplies, and fans. Hover the cursor over a port and the port details appear, including the port name, type, speed, usage, and status, as shown in [Figure 40](#). The aggregation group number is also displayed if the port is added to an aggregation group. For the description about the port number and its color, see [Figure 40](#). Similarly, you can also view the power type and operating status and the fan operating status.

Figure 40 Device information

To set the interval for refreshing device information, select one of the following options from the **Refresh Period** list:

- If you select a certain period, the system refreshes device information at the specified interval.
- If you select **Manual**, the system refreshes device information only when you click the **Refresh** button.

Configuring basic device settings

Overview

The device basic information feature provides the following functions:

- Set the system name of the device. The configured system name is displayed on the top of the navigation bar.
- Set the idle timeout period for logged-in users. The system logs an idle user off the Web for security purpose after the specified period.

Configuring system name

1. Select **Device** > **Basic** from the navigation tree.
The system name configuration page appears.

Figure 41 Configuring system name

System Name Web Idle Timeout

Set sysname

Sysname sysname * Chars.(1-30)

Items marked with an asterisk(*) are required

Apply

2. Enter the system name.
3. Click **Apply**.

Configuring idle timeout period

1. Select **Device** > **Basic** from the navigation tree.
2. Click the **Web Idle Timeout** tab.
The page for configuring the idle timeout period appears.

Figure 42 Configuring idle timeout period

System Name	Web Idle Timeout
Set idle timeout	
Idle timeout	<input type="text" value="10"/> *Minutes(1-999, Default = 10)
Items marked with an asterisk(*) are required	
<input type="button" value="Apply"/>	

3. Set the idle timeout period for logged-in users.
4. Click **Apply**.

Maintaining devices

Upgrading software

⚠ CAUTION:

Software upgrade takes a period of time. Avoid performing any operation on the Web interface during the upgrading procedure. Otherwise, the upgrade operation might be interrupted.

A boot file, also known as the system software or device software, is an application file used to boot the device. Software upgrade allows you to obtain a target application file from the local host and set the file as the boot file with the original file name to be used at the next reboot. In addition, you can select whether to reboot the device to bring the upgrade software into effect.

To upgrade software:

1. Select **Device** > **Device Maintenance** from the navigation tree.

The page for upgrading software appears.

Figure 43 Software upgrade configuration page

Software Upgrade Reboot Electronic Label Diagnostic Information

File Browse... *

File Type Main ▾

☐ If a file with the same name already exists, overwrite it without any prompt

☐ To upgrade the files of slave boards at one time

☐ Reboot after the upgrade is finished

Note:

Do not perform any operation when upgrade is in process.

The length of filename cannot exceed 47, and must end with an extension of .app or .bin.

Items marked with an asterisk(*) are required

Apply

2. Configure software upgrade parameters as described in [Table 9](#).
3. Click **Apply**.

Table 9 Configuration items

Item	Description
File	Specify the path and filename of the local application file, which must be suffixed with the .app or .bin extension.
File Type	Specify the type of the boot file for the next reboot: <ul style="list-style-type: none">• Main—Boots the device.• Backup—Boots the device when the main boot file is unavailable.

Item	Description
If a file with the same name already exists, overwrite it without any prompt	Specify whether to overwrite the file with the same name. If you do not select the option, when a file with the same name exists, a dialog box appears, telling you that the file already exists and you cannot continue the upgrade.
To upgrade the files of slave boards at one time	Specify whether to upgrade the boot file on the standby MPU (not available).
Reboot after the upgrade finished	Specify whether to reboot the device to make the upgraded software take effect after the application file is uploaded.

Rebooting the device

CAUTION:

To avoid loss of unsaved configuration after the reboot, save the configuration before rebooting the device.

To reboot the device:

1. Select **Device > Device Maintenance** from the navigation tree.
2. Click the **Reboot** tab.

The device reboot page appears.

Figure 44 Device reboot page

Software Upgrade Reboot Electronic Label Diagnostic Information

Device Reboot

Any configuration changes that have not been saved are lost when the system reboots.

☒ Check whether the current configuration is saved in the next startup configuration file.

Reboot Cancel

3. Clear the box next to "**Check whether the current configuration is saved in the next startup configuration file**" or keep it selected.
 - If you select the box, the system will examine the configuration before rebooting the device.
 - If the examination succeeds, the system will reboot the device.
 - If the examination fails, a dialog box appears, telling you that the current configuration and the saved configuration are inconsistent, and the device will not be rebooted. In this case, you need to save the current configuration manually before you can reboot the device.
 - If you do not select the box, the system will reboot the device directly.
4. Click **Reboot**.
A confirmation dialog box appears.
5. Click **OK**.

After the device reboots, you need to re-log in to the device.

Displaying the electronic label

You can view information about the device electronic label, which is also known as the permanent configuration data or archive information. The information is written into the storage medium of a device or a card during the debugging and testing processes, and includes card name, product bar code, MAC address, debugging and testing dates, and vendor name.

To view information about the electronic label:

1. Select **Device > Device Maintenance** from the navigation tree.
2. Click the **Electronic Label** tab.
The page for electronic label information appears.

Figure 45 Electronic label

Software Upgrade		Reboot		Electronic Label		Diagnostic Information	
<input type="text"/>		Device		<input type="button" value="Search"/>		Advanced Search	
Device	Slot ID	SubSlot ID	Name	Serial Number	MAC	Manufacturing Date	Vendor Name
1	1	-	HP 1910-8G-PoE+ (180W) Switch JG350A	210235A0FLB111000011	3ce5-a6cd-9a64	2011-1-11	HP

Displaying diagnostic information

Each functional module has its own running information, and generally, you can view the output information for each module one by one. To receive as much information as possible in one operation during daily maintenance or when system failure occurs, the diagnostic information module allows you to save the running statistics of multiple functional modules to a file named **default.diag**, through which you can locate problems faster.

IMPORTANT:

The generation of the diagnostic file takes a period of time. During this process, do not perform any operation on the Web page.

To open or save a diagnostic information file:

1. Select **Device > Device Maintenance** from the navigation tree.
2. Click the **Diagnostic Information** tab.
The diagnostic information page appears.

Figure 46 Diagnostic information

Software Upgrade	Reboot	Electronic Label	Diagnostic Information
<input type="button" value="Create Diagnostic Information File"/>			

- Note: The operation may take a long time. Do not perform any operation when creating diagnostic information file is in process.

3. Click **Create Diagnostic Information File**.

The system begins to generate a diagnostic information file.

After the diagnostic information file is generated, a page as shown in [Figure 47](#) appears.

4. Click **Click to Download**.

The **File Download** dialog box appears.

Figure 47 Downloading the diagnostic information file

[Click to Download](#)

- Note: The operation may take a long time. Do not perform any operation when creating diagnostic information file is in process.

Creating diagnostic information file succeeded.

5. Open this file to display diagnostic information or save it to the local host.

After the diagnostic file is successfully generated, you can view this file, or download it to the local host on the page you enter by selecting **Device > File Management**. For more information, see "[Managing files](#)."

Configuring system time

Overview

You must configure a correct system time so that the device can operate correctly with other devices. The system time module allows you to display and set the device system time and system zone on the web interface.

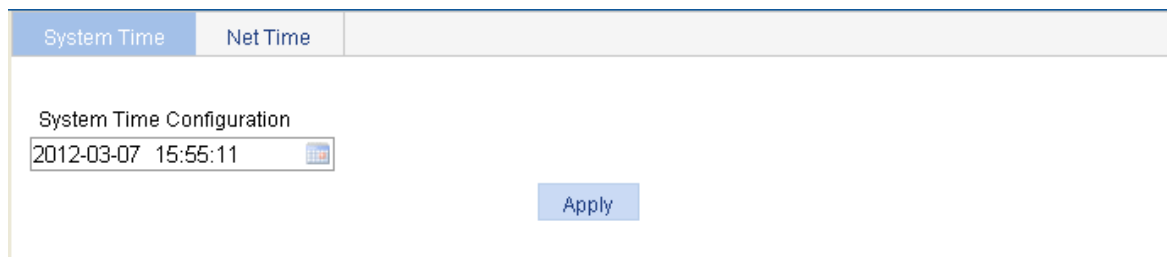

You can set the system time through manual configuration or network time protocol (NTP) automatic synchronization.

Defined in RFC 1305, the NTP synchronizes timekeeping among distributed time servers and clients. NTP can keep consistent timekeeping among all clock-dependent devices within the network and ensure a high clock precision so that the devices can provide diverse applications based on consistent time.

Displaying the current system time

To view the current system date and time, select **Device > System Time** from the navigation tree to enter the **System Time** page.

Figure 48 System time configuration page

System Time	Net Time
System Time Configuration	
2012-03-07 15:55:11 	
<button>Apply</button>	

Manually configuring the system time

1. Select **Device > System Time** from the navigation tree.
The page for configuration the system time appears.
2. Click the **System Time Configuration** text to open a calendar.

Figure 49 Calendar page

2012-03-07 15:56:38

Mar 2012

Sun	Mon	Tue	Wed	Thu	Fri	Sat
26	27	28	29	1	2	3
4	5	6	7	8	9	10
11	12	13	14	15	16	17
18	19	20	21	22	23	24
25	26	27	28	29	30	31
1	2	3	4	5	6	7

Time 15:57:14

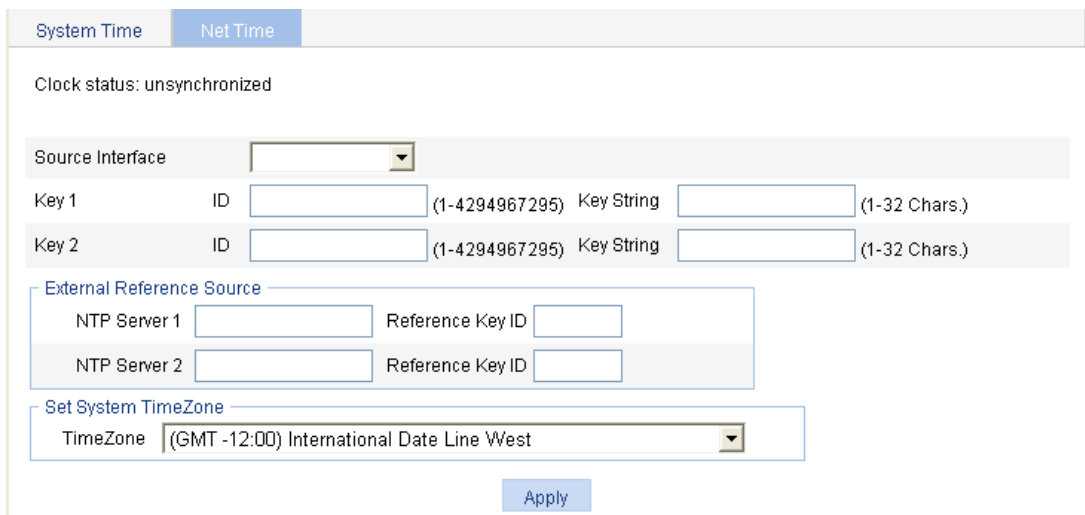

Today OK

3. Enter the system date and time in the **Time** field, or select the date and time in the calendar. To set the time on the calendar page, select one of the following methods:
 - Click **Today**. The date setting in the calendar is synchronized to the current local date configuration, and the time setting does not change.
 - Select the year, month, date, and time, and then click **OK**.
4. Click **Apply** on the system time configuration page to save your configuration.

Configuring the system time by using NTP

1. Select **Device > System Time** from the navigation tree.
 2. Click the **Network Time Protocol** tab.
- The page for configuring the system time through NTP appears.

Figure 50 NTP configuration page

3. Configure the system time as described in [Table 10](#).
4. Click **Apply**.

Table 10 Configuration items

Item		Description
Clock status		Display the synchronization status of the system clock.
Source Interface		<p>Set the source interface for an NTP message.</p> <p>This configuration uses the IP address of an interface as the source IP address in the NTP messages. If the specified source interface is down, the source IP address is the IP address of the egress interface.</p> <p> TIP:</p> <p>If you do not want the IP address of a certain interface on the local device to become the destination address of response messages, you can specify the source interface for NTP messages.</p>
Key 1		<p>Set NTP authentication key.</p> <p>The NTP authentication feature should be enabled for a system running NTP in a network that requires high security. This feature enhances the network security by means of client-server key authentication, and prohibits a client from synchronizing with a device that has failed authentication.</p>
Key 2		<p>You can set two authentication keys, each of which has a key ID and key string.</p> <ul style="list-style-type: none"> • ID—ID of a key. • Key string—A character string for MD5 authentication key.
External Reference Source	NTP Server 1/Reference Key ID	Specify the IP address of an NTP server, and configure the authentication key ID used for the association with the NTP server. Only if the key provided by the server is the same with the specified key will the device synchronize its time to the NTP server.
	NTP Server 2/Reference Key ID	<p>You can configure two NTP servers. The clients will choose the optimal reference source.</p> <p> IMPORTANT:</p> <p>The IP address of an NTP server is a unicast address, and cannot be a broadcast or a multicast address, or the IP address of the local clock source.</p>
TimeZone		Set the time zone for the system.

System time configuration example

Network requirements

As shown in [Figure 51](#):

- The local clock of Device A is set as the reference clock.
- Switch B operates in client mode, and uses Device A as the NTP server.

Configure NTP authentication on Device A and Switch B so that Switch B is to be synchronized to Device A.

Figure 51 Network diagram

Configuring the system time

1. Configure the local clock as the reference clock, with the stratum of 2. Enable NTP authentication, set the key ID to **24**, and specify the created authentication key **aNiceKey** as a trusted key. (Details not shown.)
2. On Switch B, configure Device A as the NTP server:
 - a. Select **Device > System Time** from the navigation tree.
 - b. Click the **Network Time Protocol** tab.
 - c. Enter **24** in the **ID** field and enter **aNiceKey** in the **Key String** field for key 1, enter **1.0.1.11** in the **NTP Server 1** field and enter **24** in the **Reference Key ID** field.
 - d. Click **Apply**.

Figure 52 Configuring Device A as the NTP server of Switch B

System Time | Net Time

Clock status: unsynchronized

Source Interface:

Key 1	ID	24	(1-4294967295)	Key String	aNiceKey	(1-32 Chars.)
Key 2	ID		(1-4294967295)	Key String		(1-32 Chars.)

External Reference Source

NTP Server 1	1.0.1.11	Reference Key ID	24
NTP Server 2		Reference Key ID	

Set System TimeZone

TimeZone: (GMT -12:00) International Date Line West

Apply

Verifying the configuration

After the configuration, verify that Device A and Switch B have the same system time.

Configuration guidelines

When you configure the system time, follow these guidelines:

- A device can act as a server to synchronize the clock of other devices only after its clock has been synchronized. If the clock of a server has a stratum level higher than or equal to the level of a client's clock, the client will not synchronize its clock to the server's.

- The synchronization process takes a period of time. The clock status might be displayed as **unsynchronized** after your configuration. In this case, you can refresh the page to view the clock status and system time later on.
- If the system time of the NTP server is ahead of the system time of the device, and the time gap exceeds the web idle time specified on the device, all online web users are logged out because of timeout after the synchronization finishes. In this case, you can log in to the device again.

Configuring syslog

Overview

System logs contain a large amount of network and device information, including running status and configuration changes. System logs are an important way for administrators to know network and device running status. With system logs, administrators can take corresponding actions against network problems and security problems.

The system can send system logs to various destinations such as a log host or the Web interface.

Displaying syslogs

The Web interface provides abundant search and sorting functions. You can view syslogs through the Web interface conveniently.

To display syslogs:

1. Select **Device** > **Syslog** from the navigation tree.

The page for displaying syslogs appears.

Figure 53 Displaying syslogs

Loglist

Loghost

Log Setup

This page implements the system log management function.

Reset

Refresh

**TIP:**

- You can click **Reset** to clear all system logs saved in the log buffer on the Web interface.
- You can click **Refresh** to manually refresh the page, or you can set the refresh interval on the **Log Setup** page to enable the system to automatically refresh the page periodically. For more information, see "[Setting buffer capacity and refresh interval.](#)"

2. View system logs.**Table 11** Field description

Field	Description
Time/Date	Displays the time/date when system logs are generated.
Source	Displays the module that generates system logs.
Level	Displays the system information levels. The information is classified into eight levels by severity: <ul style="list-style-type: none">• Emergency—The system is unavailable.• Alert—Action must be taken immediately.• Critical—Critical conditions.• Error—Error conditions.• Warning—Warning conditions.• Notification—Normal but significant condition.• Information—Informational messages.• Debug—Debug-level messages.
Digest	Displays the brief description of system logs.
Description	Displays the contents of system logs.

Setting the log host

You can set the loghost on the Web interface to enable the system to output syslogs to the log host. You can specify at most four different log hosts.

To set the log host:

1. Select **Device > Syslog** from the navigation tree.
2. Click the **Loghost** tab.

The loghost configuration page appears.

Figure 54 Setting loghost

Refresh Interval	<p>Set the refresh period on the log information displayed on the Web interface.</p> <p>You can select manual refresh or automatic refresh:</p> <ul style="list-style-type: none">• Manual—Click Refresh to refresh the Web interface when displaying log information.• Automatic—Select to refresh the Web interface every 1 minute, 5 minutes, or 10 minutes.

Managing the configuration

You can back up, restore, save, and reset the configuration of the device.

Backing up the configuration

The configuration backup function allows you to perform the following tasks:

- View the configuration file (**.cfg** file) for the next startup, or the next-startup configuration file.
- Back up the next-startup configuration file (**.cfg** file) to your host.

To back up the configuration:

1. Select **Device > Configuration** from the navigation tree to enter the configuration backup page.

Figure 56 Backing up the configuration

2. Click the upper **Backup** button.
The file download dialog box appears.
3. View the **.cfg** file or save the file locally.

Restoring the configuration

You can upload the **.cfg** file from your host to the device for the next startup. The restored configuration takes effect at the next device startup.

To restore the configuration:

1. Select **Device > Configuration** from the navigation tree.
2. Click the **Restore** tab.

Figure 57 Restoring the configuration

Backup Restore Save Initialize

Restore the Configuration File:

Browse... (the file with the extension ".cfg")

Items marked with an asterisk(*) are required

Apply

3. Click the upper **Browse** button.
The file upload dialog box appears.
4. Select the **.cfg** file to be uploaded, and click **Apply**.

Saving the configuration

You can save the running configuration to the next-startup configuration file (**.cfg** file).

Operation guidelines

Saving the configuration takes some time.

The device does not allow two or more users to save the configuration at the same time. If such a case occurs, the system prompts the users other than the first one to try again later.

After a software upgrade, the device loads by default the next-startup configuration file specified before the software upgrade when it starts up. When you save the running configuration after changing the configuration, the device automatically backs up the next-startup configuration file before saving the running configuration. For example, if the next-startup configuration file specified before the software upgrade is startup.cfg, the device backs up the file to file _startup_bak.cfg and saves the running configuration to file startup.cfg.

Operation procedure

You can save the configuration in fast mode or common mode.

To save the configuration in fast mode, click the **Save** button at the upper right of the auxiliary area.

Figure 58 Saving the configuration

Note: Click **Save Current Settings** to save the current configuration.

To save the configuration in common mode:

1. Select **Device > Configuration** from the navigation tree.
2. Click the **Save** tab.
3. Click **Save Current Settings**.

Resetting the configuration

Resetting the configuration restores the system to the factory defaults, deletes the current configuration file, and reboots the device.

To reset the configuration:

1. Select **Device > Configuration** from the navigation tree.
2. Click the **Initialize** tab.
3. Click **Restore Factory-Default Settings**.

Figure 59 Resetting the configuration

Note: Click **Restore Factory-Default Settings** to restore and initialize the factory-default settings and reboot.

Managing files

The device saves files such as the host software file and configuration file on its storage media. The file management function allows you to manage the files on the storage media.

Displaying files

1. Select **Device > File Management** from the navigation tree.

Figure 60 File management page

The screenshot displays the 'File Management' interface. At the top, there's a header 'File Management'. Below it, a section shows 'Please select disk' with a dropdown menu set to 'flash'. To the right, storage statistics are shown: 'Used space: 65.13 MB', 'Free space: 30.88 MB', and 'Capacity: 96.00 MB'. The main area is a table with columns: 'File', 'Size(KB)', and 'Operation'. The table lists ten files, each with a checkbox in the first column and a trash icon in the 'Operation' column. Below the table, there's a pagination bar showing '10 records', '15' items per page, 'page 1/1', and 'record 1-10'. It also includes 'First', 'Prev', 'Next', 'Last' navigation links and a 'GO' button. Below the pagination are 'Download File' and 'Remove File' buttons. At the bottom, there's an 'Upload File' section with a 'Please select disk' dropdown (set to 'flash'), a 'File' input field, and a 'Browse...' button. A note states: 'Note: Do not perform any operation when upload is in process.' An 'Apply' button is at the bottom right of the upload section.

	File	Size(KB)	Operation
<input type="checkbox"/>	flash:/default.diag	500.688	
<input type="checkbox"/>	flash:/a5120si-cmw520-r1509.bin	13,445.742	
<input type="checkbox"/>	flash:/config.cwmp	9.629	
<input type="checkbox"/>	flash:/startup.cfg	1.036	
<input type="checkbox"/>	flash:/a5120si-cmw520-f1509.bin	13,647.867	
<input type="checkbox"/>	flash:/system.xml	0.032	
<input type="checkbox"/>	flash:/bootfile.bin	13,590.281	
<input type="checkbox"/>	flash:/v1910-cmw520-r1111.bin	10,334.57	
<input type="checkbox"/>	flash:/qx-s4000-v534.bin	13,492.523	
<input type="checkbox"/>	flash:/logfile/logfile.log	80.096	

2. Select a medium from the **Please select disk** list.
The following information is displayed:
 - Medium Information, including the used space, free space, and the capacity of the medium.
 - File information, including all files on the medium and the file sizes.

Downloading a file

1. Select **Device > File Management** from the navigation tree to enter the file management page. See [Figure 60](#).
2. From the **Please select disk** list, select the medium where the file to be downloaded resides.

3. Select the file from the list.
Only one file can be downloaded at a time.
4. Click **Download File**.
The **File Download** dialog box appears.
5. Open the file or save the file to a specified path.

Uploading a file

Uploading a file takes some time. HP recommends not performing any operation in the Web interface during the upgrade.

To upload a file:

1. Select **Device > File Management** from the navigation tree to enter the file management page.
See [Figure 60](#).
2. In the **Upload File** area, select the medium for saving the file from the **Please select disk** list.
3. Click **Browse** to navigate to the file to be uploaded.
4. Click **Apply**.

Removing a file

1. Select **Device > File Management** from the navigation tree to enter the file management page.
See [Figure 60](#).
2. Click the  icon of a file to remove the file, or select a file from the file list and click **Remove File**.

To remove multiple files, repeat step 2, or select the files from the file list and click **Remove File**.

Managing ports

You can use the port management feature to set and view the operation parameters of a Layer 2 Ethernet port and an aggregate interface.

- For a Layer 2 Ethernet port, these operation parameters include its state, rate, duplex mode, link type, PVID, MDI mode, flow control settings, MAC learning limit, and storm suppression ratios.
- For an aggregate interface, these operation parameters include its state and MAC learning limit.

Setting operation parameters for a port

1. Select **Device > Port Management** from the navigation tree.
2. Click the **Setup** tab to enter the page, as shown in [Figure 61](#).

Table 13 Configuration items

Item	Description
Port State	<p>Enable or disable the port.</p> <p>After you modify the operation parameters of a port, you might need to disable and then enable the port to make the modifications take effect.</p>
Speed	<p>Set the transmission rate of the port:</p> <ul style="list-style-type: none">• 10—10 Mbps.• 100—100 Mbps.• 1000—1000 Mbps.• Auto—Autonegotiation.• Auto 10—Autonegotiated to 10 Mbps.• Auto 100—Autonegotiated to 100 Mbps.• Auto 1000—Autonegotiated to 1000 Mbps.• Auto 10 100—Autonegotiated to 10 or 100 Mbps.• Auto 10 1000—Autonegotiated to 10 or 1000 Mbps.• Auto 100 1000—Autonegotiated to 100 or 1000 Mbps.• Auto 10 100 1000—Autonegotiated to 10, 100, or 1000 Mbps.
Duplex	<p>Set the duplex mode of the port:</p> <ul style="list-style-type: none">• Auto—Autonegotiation.• Full—Full duplex.• Half—Half duplex.
Link Type	<p>Set the link type of the current port, which can be access, hybrid, or trunk. For more information, see "Configuring VLANs."</p> <p>To change the link type of a port from trunk to hybrid or vice versa, you must first set its link type to access.</p>
PVID	<p>Set the default VLAN ID of the interface. For more information about setting the PVID, see "Configuring VLANs."</p> <p>To make sure a link correctly transmits packets, the trunk or hybrid ports at the two ends of the link must have the same PVID.</p>

Item	Description
MDI	<p>Set the Medium Dependent Interface (MDI) mode of the port.</p> <p>You can use two types of Ethernet cables to connect Ethernet devices: crossover cable and straight-through cable. To accommodate these two types of cables, an Ethernet port can operate in one of the following MDI modes: across, normal, and auto.</p> <p>An Ethernet port is composed of eight pins. By default, each pin has its particular role. For example, pin 1 and pin 2 are used for transmitting signals, and pin 3 and pin 6 are used for receiving signals. You can change the pin roles by setting the MDI mode.</p> <ul style="list-style-type: none"> For an Ethernet port in across mode, pin 1 and pin 2 are used for transmitting signals, and pin 3 and pin 6 are used for receiving signals. The pin roles are not changed. For an Ethernet port in auto mode, the pin roles are decided through autonegotiation. For an Ethernet port in normal mode, the pin roles are changed. Pin 1 and pin 2 are used for receiving signals, and pin 3 and pin 6 are used for transmitting signals. <p>To enable correct communication, you must connect the local transmit pins to the remote receive pins.</p> <p>When you configure the MDI mode, follow these guidelines:</p> <ul style="list-style-type: none"> Typically, use the auto mode. The other two modes are used only when the device cannot determine the cable type. When straight-through cables are used, the local MDI mode must be different from the remote MDI mode. When crossover cables are used, the local MDI mode must be the same as the remote MDI mode, or the MDI mode of at least one end must be set to auto.
Flow Control	<p>Enable or disable flow control on the port.</p> <p>With flow control enabled at both sides, when traffic congestion occurs on the ingress port, the ingress port sends a Pause frame notifying the egress port to temporarily suspend the sending of packets. The egress port is expected to stop sending any new packet when it receives the Pause frame. In this way, flow control helps to avoid dropping of packets.</p> <p>Flow control works only after it is enabled on both the ingress and egress ports.</p>
Power Save	<p>Enable or disable auto power down on the port.</p> <p>With auto power down enabled, when an Ethernet port does not receive any packet for a certain period of time, it automatically enters the power save mode and resumes its normal state upon the arrival of a packet.</p> <p>Support for this configuration item varies with device models.</p>
Max MAC Count	<p>Set the MAC learning limit on the port:</p> <ul style="list-style-type: none"> User Defined—Select this option to set the limit manually. No Limited—Select this option to set no limit.

Item	Description
Broadcast Suppression	<p>Set broadcast suppression on the port:</p> <ul style="list-style-type: none"> • ratio—Sets the maximum percentage of broadcast traffic to the total bandwidth of an Ethernet port. When you select this option, you must enter a percentage in the box below. • pps—Sets the maximum number of broadcast packets that can be forwarded on an Ethernet port per second. When you select this option, you must enter a number in the box below. • kbps—Sets the maximum number of kilobits of broadcast traffic that can be forwarded on an Ethernet port per second. When you select this option, you must enter a number in the box below. <p> IMPORTANT:</p> <p>Do not configure this item if the storm constrain function for broadcast traffic is enabled on the port. Otherwise, the suppression result is not determined. To set storm constrain for broadcast traffic on a port, select Device > Storm Constrain.</p>
Multicast Suppression	<p>Set multicast suppression on the port:</p> <ul style="list-style-type: none"> • ratio—Sets the maximum percentage of multicast traffic to the total bandwidth of an Ethernet port. When you select this option, you must enter a percentage in the box below. • pps—Sets the maximum number of multicast packets that can be forwarded on an Ethernet port per second. When you select this option, you must enter a number in the box below. • kbps—Sets the maximum number of kilobits of multicast traffic that can be forwarded on an Ethernet port per second. When you select this option, you must enter a number in the box below. <p> IMPORTANT:</p> <p>Do not configure this item if the storm constrain function for multicast traffic is enabled on the port. Otherwise, the suppression result is not determined. To set storm constrain for multicast traffic on a port, select Device > Storm Constrain.</p>
Unicast Suppression	<p>Set unicast suppression on the port:</p> <ul style="list-style-type: none"> • ratio—Sets the maximum percentage of unicast traffic to the total bandwidth of an Ethernet port. When you select this option, you must enter a percentage in the box below. • pps—Sets the maximum number of unicast packets that can be forwarded on an Ethernet port per second. When you select this option, you must enter a number in the box below. • kbps—Sets the maximum number of kilobits of unicast traffic that can be forwarded on an Ethernet port per second. When you select this option, you must enter a number in the box below. <p> IMPORTANT:</p> <p>Do not configure this item if the storm constrain function for unicast traffic is enabled on the port. Otherwise, the suppression result is not determined. To set storm constrain for unicast traffic on a port, select Device > Storm Constrain.</p>
Selected Ports	<p>Interface or interfaces that you have selected from the chassis front panel and the aggregate interface list below, for which you have set operation parameters.</p> <p>You can set only the state and MAC learning limit for an aggregate interface.</p>

NOTE:

If you set operation parameters that a port does not support, you are notified of invalid settings and might fail to set the supported operation parameters for the port or other ports.

Displaying port operation parameters

Displaying a specified operation parameter for all ports

1. Select **Device > Port Management** from the navigation tree to enter the **Summary** page by default.
2. Select the option for a parameter you want to view.

The parameter information for all the ports is displayed in the lower part of the page, as shown in Figure 62.

Port management configuration example

Network requirements

As shown in [Figure 64](#):

- Server A, Server B, and Server C are connected to GigabitEthernet 1/0/1, GigabitEthernet 1/0/2, and GigabitEthernet 1/0/3 on the switch, respectively. The rates of the network adapters of these servers are all 1000 Mbps.
- The switch connects to the external network through GigabitEthernet 1/0/4 whose rate is 1000 Mbps.

To avoid congestion at the egress port, GigabitEthernet 1/0/4, configure the autonegotiation rate range on GigabitEthernet 1/0/1, GigabitEthernet 1/0/2, and GigabitEthernet 1/0/3 as 100 Mbps.

Figure 64 Network diagram

Configuring the switch

1. Set the rate of GigabitEthernet 1/0/4 to 1000 Mbps:
 - a. Select **Device** > **Port Management** from the navigation tree
 - b. Click the **Setup** tab to enter the page, as shown in [Figure 65](#).
 - c. Select **1000** from the **Speed** list.
 - d. Select **4** on the chassis front panel. **4** represents port GigabitEthernet 1/0/4.
 - e. Click **Apply**.

Figure 65 Configuring the rate of GigabitEthernet 1/0/4

Feature Summary:

Configuring port mirroring

Port mirroring refers to the process of copying the packets passing through a port to the monitor port connecting to a monitoring device for packet analysis.

Terminology

Mirroring source

The mirroring source can be one or more monitored ports, called source ports. The device where the ports reside is called a "source device." Packets (called "mirrored packets") passing through them are copied to a port connecting to a monitoring device for packet analysis.

Mirroring destination

The mirroring destination is the destination port (also known as the monitor port) of mirrored packets and connects to the data monitoring device. The device where the monitor port resides is called the "destination device". The monitor port forwards mirrored packets to its connected monitoring device.

A monitor port might receive multiple duplicates of a packet in some cases because it can monitor multiple mirroring sources. For example, assume that Port 1 is monitoring bidirectional traffic on Port 2 and Port 3 on the same device. If a packet travels from Port 2 to Port 3, two duplicates of the packet will be received on Port 1.

Mirroring direction

The mirroring direction indicates that the inbound, outbound, or bidirectional traffic can be copied on a mirroring source.

- **Inbound**—Copies packets received on a mirroring source.
- **Outbound**—Copies packets sent out of a mirroring source.
- **Bidirectional**—Copies packets both received and sent on a mirroring source.

Mirroring group

Port mirroring is implemented through mirroring groups. The mirroring source and mirroring destination must belong to a mirroring group.

Port mirroring implementation

HP 1910 switch series supports local port mirroring, in which case the mirroring source and the mirroring destination are on the same device. A mirroring group that contains the mirroring source and the mirroring destination on the same device is called a "local mirroring group."

Figure 68 Local port mirroring implementation

As shown in [Figure 68](#), the source port GigabitEthernet 1/0/1 and monitor port GigabitEthernet 1/0/2 reside on the same device. Packets of GigabitEthernet 1/0/1 are copied to GigabitEthernet 1/0/2, which then forwards the packets to the data monitoring device for analysis.

Configuration restrictions and guidelines

When you configure port mirroring, follow these restrictions and guidelines:

- A local mirroring group can contain multiple source ports, but only one monitor port.
- Do not enable the spanning tree feature on the monitor port.
- Use a monitor port only for port mirroring to make sure the data monitoring device receives and analyzes only the mirrored traffic rather than a mix of mirrored traffic and other forwarded traffic.

Recommended configuration procedures

Step	Remarks
1. Configure a local mirroring group	Required. For more information, see " Configuring a mirroring group. " Select the mirroring group type local in the Type list.
2. Configure source ports for the mirroring group	Required. For more information, see " Configuring ports for the mirroring group. " Select the port type Mirror Port .
3. Configure the monitor port for the mirroring group	Required. For more information, see " Configuring ports for the mirroring group. " Select the port type Monitor Port .

Configuring a mirroring group

1. From the navigation tree, select **Device > Port Mirroring**.
2. Click **Add** to enter the page for adding a mirroring group.

Configuring a loopback test

Overview

You can check whether an Ethernet port operates correctly by performing Ethernet port loopback test. During the test time, the port cannot forward data packets correctly.

Ethernet port loopback test has the following types:

- **Internal loopback test**—Establishes self loop in the switching chip and checks whether there is a chip failure related to the functions of the port.
- **External loopback test**—Uses a loopback plug on the port. Packets forwarded by the port will be received by itself through the loopback plug. The external loopback test can be used to check whether there is a hardware failure on the port.

Configuration restrictions and guidelines

When you configure a loopback test, follow these restrictions and guidelines:

- When a port is physically down, you cannot perform an external loopback test on the port.
- After a port is shut down manually, you can perform neither internal test nor external test on the port.
- When a port is under a loopback test, you cannot apply **Rate**, **Duplex**, **Cable Type**, and **Port Status** configuration to the port.
- An Ethernet port operates in full duplex mode when a loopback test is performed. It restores its original duplex mode after the loopback test.

Configuration procedure

1. From the navigation tree, select **Device > Loopback**.
The loopback test configuration page appears, as shown in [Figure 78](#).

Figure 78 Loopback test page

Loopback

Testing type: ☒ External ☐ Internal

HP 1910-8G-PoE+...

Test

Result:

2. Select **External** or **Internal** for loopback test type.
3. Select an Ethernet interface from the chassis front panel.
4. Click **Test**.

After the test is complete, the system displays the loopback test result, as shown in [Figure 79](#).

Figure 79 Loopback test result

Test

Result:
GigabitEthernet1/0/2: Loop internal succeeded!

Configuring VCT

Overview

You can use the Virtual Cable Test (VCT) function to check the status of the cable connected to an Ethernet port on the device. The result is returned in less than 5 seconds. The test covers whether short circuit or open circuit occurs on the cable and the length of the faulty cable.

NOTE:

A link in the up state goes down and then up automatically if you perform this operation on one of the Ethernet interfaces forming the link.

Testing cable status

1. Select **Device** > **VCT** from the navigation tree to enter the page for testing cable status.
2. Select the port you want to test on the chassis front panel.
3. Click **Test**.

The test result is returned within 5 seconds and displayed in the **Result** field.

Figure 80 Testing the status of the cable connected to an Ethernet port

The result displays the cable status and length:

- The cable status can be normal, abnormal, abnormal (open), abnormal (short), or failure.
- When a cable is normal, the cable length displayed is the total length of the cable.
- When a cable is abnormal, the cable length displayed is the length between the current port and the location where fault occurs.
- The cable length detected can have an error of up to 5 meters.

Configuring the flow interval

Overview

With the flow interval module, you can view the number of packets and bytes sent/received by a port and the bandwidth utilization of the port over the specified interval.

Setting the traffic statistics generating interval

1. Select **Device** > **Flow interval** from the navigation tree.
2. Click the **Interval Configuration** tab.

Figure 81 Setting the traffic statistics generating interval

NOTE:

When the bandwidth utilization is lower than 1%, 1% is displayed.

Configuring storm constrain

Overview

The storm constrain function suppresses packet storms in an Ethernet. This function compares broadcast, multicast, and unknown unicast traffic regularly with their respective traffic thresholds on an Ethernet port. For each type of traffic, storm constrain provides a lower threshold and a higher threshold.

For management purposes, you can configure the port to output threshold event traps and log messages when monitored traffic exceeds the upper threshold or falls below the lower threshold from the upper threshold.

Depending on your configuration, when a particular type of traffic exceeds its upper threshold, the port does either of the following:

- **Block this type of traffic, while forwarding other types of traffic**—Even though the port does not forward the blocked traffic, it still counts the traffic. When the blocked traffic drops below the lower threshold, the port begins to forward the traffic.
- **Shuts down automatically**—The port shuts down automatically and stops forwarding all types of traffic. The port cannot automatically restore even when the blocked traffic drops down below the lower threshold. To bring up the port, select **Device > Port Management** to configure the port (see "[Managing ports](#)"), or cancel the storm constrain setting on the port.

Alternatively, you can configure the storm suppression function to control a specific type of traffic. For more information about the storm suppression function, see "[Managing ports](#)."

Do not enable storm constrain and storm suppression at the same time on an Ethernet port. Otherwise, the traffic suppression result is not determined. For example, with unknown unicast storm suppression enabled on a port, do not enable storm constrain for unknown unicast traffic on the port.

Setting the traffic statistics generating interval

1. Select **Device > Storm Constrain** from the navigation tree to enter the storm constrain configuration page.
2. In the **Interval for generating traffic statistics** field, enter the traffic statistics generating interval for storm constrain.
3. Click **Apply**.

Select ports	Select ports from the chassis front panel to apply the storm constrain settings to them.

Configuring RMON

Overview

Remote Monitoring (RMON) is an enhancement to SNMP for remote device management and traffic monitoring. An RMON monitor, typically the RMON agent embedded in a network device, periodically or continuously collects traffic statistics for the network attached to a port, and when a statistic crosses a threshold, logs the crossing event and sends a trap to the management station.

RMON uses SNMP traps to notify NMSs of exceptional conditions. RMON SNMP traps report various events, including traffic events such as broadcast traffic threshold exceeded. In contrast, SNMP standard traps report device operating status changes such as link up, link down, and module failure.

RMON enables proactive monitoring and management of remote network devices and subnets. The managed device can automatically send a trap when a statistic crosses an alarm threshold, and the NMS does not need to constantly poll MIB variables and compare the results. As a result, network traffic is reduced.

Working mechanism

RMON monitors typically take one of the following forms:

- **Dedicated RMON probes.** NMSs can obtain management information from RMON probes directly and control network resources. By using this method, NMSs can obtain all RMON MIB information.
- **RMON agents embedded in network devices.** NMSs exchange data with RMON agents by using basic SNMP operations to gather network management information. This method consumes the resources of managed network devices, and most RMON agent implementations only provide four groups of MIB information, alarm, event, history, and statistics.

HP devices provide the embedded RMON agent function. You can configure your device to collect and report traffic statistics, error statistics, and performance statistics.

RMON groups

Among the RFC 2819 defined RMON groups, HP implements the statistics group, history group, event group, and alarm group supported by the public MIB.

Statistics group

The statistics group defines that the system collects statistics on various traffic information on an interface (at present, only Ethernet interfaces are supported) and saves the statistics in the Ethernet statistics table (etherStatsTable) for query convenience of the management device. It provides statistics about network collisions, CRC alignment errors, undersize/oversize packets, broadcasts, multicasts, bytes received, packets received, and so on.

After the creation of a statistics entry on an interface, the statistics group starts to collect traffic statistics on the interface. The result of the statistics is a cumulative sum.

History group

The history group defines that the system periodically collects statistics on traffic information at an interface and saves the statistics in the history record table (etherHistoryTable) for query convenience of the management device. The statistics data includes bandwidth utilization, number of error packets, and total number of packets.

A history group collects statistics on packets received on the interface during each period, which can be configured through the command line interface (CLI).

Event group

The event group defines event indexes and controls the generation and notifications of the events triggered by the alarms defined in the alarm group. The events can be handled in one of the following ways:

- **Log**—Logs event related information (the time of the event occurred, contents of the event, and so on) in the event log table of the RMON MIB of the device, and thus the management device can check the logs through the SNMP GET operation.
- **Trap**—Sends a trap to notify the occurrence of this event to the network management station (NMS).
- **Log-Trap**—Logs event information in the event log table and sending a trap to the NMS.
- **None**—No action.

Alarm group

The RMON alarm group monitors alarm variables, such as the count of incoming packets (etherStatsPkts) on an interface. After you define an alarm entry, the system gets the value of the monitored alarm variable at the specified interval. When the value of the monitored variable is greater than or equal to the rising threshold, a rising event is triggered. When the value of the monitored variable is smaller than or equal to the falling threshold, a falling event is triggered. The event is then handled as defined in the event group.

If an alarm entry crosses a threshold multiple times in succession, the RMON agent generates an alarm event only for the first crossing. For example, if the value of a sampled alarm variable crosses the rising threshold multiple times before it crosses the falling threshold, only the first crossing triggers a rising alarm event, as shown in [Figure 85](#).

Figure 85 Rising and falling alarm events

RMON configuration task list

Configuring the RMON statistics function

RMON statistics function can be implemented by either the statistics group or the history group, but the objects of the statistics are different. You can choose to configure a statistics group or a history group accordingly.

- A statistics object of the statistics group is a variable defined in the Ethernet statistics table, and the recorded content is a cumulative sum of the variable from the time the statistics entry is created to the current time. Perform the tasks in [Table 20](#) to configure RMON Ethernet statistics function.
- A statistics object of the history group is the variable defined in the history record table, and the recorded content is a cumulative sum of the variable in each period. Perform the tasks in [Table 21](#) to configure RMON history statistics function.

Table 20 RMON statistics group configuration task list

Task	Remarks
Configuring a statistics entry	Required.
	You can create up to 100 statistics entries in a statistics table.
	After a statistics entry is created on an interface, the system collects various traffic statistics on the interface, including network collisions, CRC alignment errors, undersize/oversize packets, broadcasts, multicasts, bytes received, and packets received. The statistics are cleared at a reboot.
	 IMPORTANT:
	Only one statistics entry can be created for one interface.

Table 21 RMON history group configuration task list

Task	Remarks
Configuring a history entry	Required.
	You can create up to 100 history entries in a history table.
	After an entry is created, the system periodically samples the number of packets received/sent on the current interface, and saves the statistics as an instance under the leaf node of the etherHistoryEntry table.
	 IMPORTANT:
	When you create an entry, if the value of the specified sampling interval is identical to that of the existing history entry, the system considers their configurations are the same and the creation fails.

Configuring the RMON alarm function

If you need to configure that the managed device sends a trap to the NMS when it triggers an alarm event, you should configure the SNMP agent as described in "SNMP configuration" before configuring the RMON alarm function.

Perform the tasks in [Table 22](#) to configure RMON alarm function.

Table 22 RMON alarm configuration task list

Task	Remarks
Configuring a statistics entry	<p>Required.</p> <p>You can create up to 100 statistics entries in a statistics table.</p> <p>As the alarm variables that can be configured through the web interface are MIB variables that defined in the history group or the statistics group, you must make sure the RMON Ethernet statistics function or the RMON history statistics function is configured on the monitored Ethernet interface.</p> <p>After a statistics entry is created on an interface, the system collects various traffic statistics on the interface, including network collisions, CRC alignment errors, undersize/oversize packets, broadcasts, multicasts, bytes received, and packets received. The statistics are cleared at a reboot.</p> <p>! IMPORTANT:</p> <p>Only one statistics entry can be created for one interface.</p>
Configuring an event entry	<p>Required.</p> <p>You can create up to 60 event entries for an event table.</p> <p>An event entry defines event indexes and the actions the system will take, including log the event, send a trap to the NMS, take no action, and log the event and send a trap to the NMS.</p> <p>! IMPORTANT:</p> <p>An entry cannot be created if the values of the specified alarm variable, sampling interval, sampling type, rising threshold and falling threshold are identical to those of an existing entry in the system.</p>
Configuring an alarm entry	<p>Required.</p> <p>You can create up to 60 alarm entries for an alarm table.</p> <p>With an alarm entry created, the specified alarm event will be triggered when an abnormality occurs, and the alarm event defines how to deal with the abnormality.</p> <p>! IMPORTANT:</p> <p>An entry cannot be created if the values of the specified event description, owners, and actions are identical to those of an existing entry in the system.</p>

Displaying RMON running status

After you configure the RMON statistics function or the alarm function, you can view RMON running status and verify the configuration by performing tasks in [Table 23](#).

Table 23 Displaying RMON running status

Task	Remarks
Displaying RMON statistics	View the interface statistics during the period from the time the statistics entry is created to the time the page is displayed. The statistics are cleared after the device reboots.
Displaying RMON history sampling information	After you have created a history control entry on an interface, the system calculates the information of the interface periodically and saves the information to the etherHistoryEntry table. You can perform this task to view the entries in this table. And the number of history sampling records that can be displayed and the history sampling interval are specified when you configure the history group.

Task	Remarks
Displaying RMON event logs	If you have configured the system to log an event after the event is triggered when you configure the event group, the event is recorded into the RMON log. You can perform this task to display the details of the log table.

Configuring a statistics entry

1. Select **Device** > **RMON** from the navigation tree.
The **Statistics** tab page appears.

Event Index	Log Index	Log Time	Description	
1	1	2011-5-16 16:18:37	The 1.3.6.1.2.1.16.1.1.1.4.1 defined in alarmEntry 1, uprise 10000000 with alarm value 11779194. Alarm sample type is absolute	

Refresh

In this example, event 1 has generated one log, which is triggered because the alarm value (11779194) exceeds the rising threshold (10000000). The sampling type is absolute.

RMON configuration example

Network requirements

As shown in Figure 97, Agent is connected to a remote NMS across the Internet. Create an entry in the RMON Ethernet statistics table to gather statistics on GigabitEthernet 1/0/1 with the sampling interval being ten seconds, and perform corresponding configurations so that the system will log the event when the number of bytes received on the interface more than 1000 or less than 100.

Figure 97 Network diagram

Configuration procedure

1. Configure RMON to gather statistics for interface GigabitEthernet 1/0/1:
 - a. Select **Device** > **RMON** from the navigation tree.
The **Statistics** tab page appears.
 - b. Click **Add**.
The page in Figure 98 appears.
 - c. Select **GigabitEthernet1/0/1** from the **Interface Name** list, type **user1** in the **Owner** field, and click **Apply**.

Shutdown	<p>Shut down the port.</p> <p>ⓘ IMPORTANT:</p> <p>An energy saving policy can have all the three energy saving schemes configured, of which the shutdown scheme takes the highest priority.</p>

Configuring SNMP

Overview

Simple Network Management Protocol (SNMP) is an Internet standard protocol widely used for a management station to access and operate the devices on a network, regardless of their vendors, physical characteristics and interconnect technologies.

SNMP enables network administrators to read and set the variables on managed devices for state monitoring, troubleshooting, statistics collection, and other management purposes.

SNMP mechanism

The SNMP framework comprises the following elements:

- **SNMP manager**—Works on an NMS to monitor and manage the SNMP-capable devices in the network.
- **SNMP agent**—Works on a managed device to receive and handle requests from the NMS, and send traps to the NMS when some events, such as interface state change, occur.
- **Management Information Base (MIB)**—Specifies the variables (for example, interface status and CPU usage) maintained by the SNMP agent for the SNMP manager to read and set.

Figure 105 Relationship between an NMS, agent and MIB

A MIB stores variables called "nodes" or "objects" in a tree hierarchy and identifies each node with a unique OID. An OID is a string of numbers that describes the path from the root node to a leaf node. For example, object B in [Figure 106](#) is uniquely identified by the OID {1.2.1.1}.

Figure 106 MIB tree

SNMP provides the following basic operations:

- **Get**—The NMS retrieves SNMP object nodes in an agent MIB.
- **Set**—The NMS modifies the value of an object node in an agent MIB.

- **Notifications**—Includes traps and informs. SNMP agent sends traps or informs to report events to the NMS. The difference between these two types of notification is that informs require acknowledgement but traps do not. The device supports only traps.

SNMP protocol versions

HP supports SNMPv1, SNMPv2c, and SNMPv3. An NMS and an SNMP agent must use the same SNMP version to communicate with each other.

- **SNMPv1**—Uses community names for authentication. To access an SNMP agent, an NMS must use the same community name as set on the SNMP agent. If the community name used by the NMS is different from the community name set on the agent, the NMS cannot establish an SNMP session to access the agent or receive traps and notifications from the agent.
- **SNMPv2c**—Uses community names for authentication. SNMPv2c is compatible with SNMPv1, but supports more operation modes, data types, and error codes.
- **SNMPv3**—Uses a user-based security model (USM) to secure SNMP communication. You can configure authentication and privacy mechanisms to authenticate and encrypt SNMP packets for integrity, authenticity, and confidentiality.

Recommended configuration procedure

SNMPv3 differs from SNMPv1 and SNMPv2c in many aspects. Their configuration procedures are described in separate sections.

Table 31 SNMPv1 or SNMPv2c configuration task list

Task	Remarks
1. Enabling SNMP agent	<p>Required.</p> <p>By default, the SNMP agent function is disabled.</p> <p> IMPORTANT:</p> <p>If SNMP agent is disabled, all SNMP agent-related configurations will be removed.</p>
2. Configuring an SNMP view	<p>Optional.</p> <p>After creating SNMP views, you can specify an SNMP view for an SNMP community to limit the MIB objects that can be accessed by the SNMP community.</p>
3. Configuring an SNMP community	<p>Required.</p>
4. Configuring the SNMP trap function	<p>Optional.</p> <p>Allows you to configure that the agent can send SNMP traps to the NMS, and configure information about the target host (usually the NMS) of the SNMP traps.</p> <p>The SNMP agent sends traps to inform the NMS of important events, such as a reboot.</p> <p>By default, an agent is allowed to send SNMP traps to the NMS.</p>
5. Displaying SNMP packet statistics	<p>Optional.</p>

Table 32 SNMPv3 configuration task list

Task	Remarks
1. Enabling SNMP agent	<p>Required.</p> <p>By default, the SNMP agent function is disabled.</p> <p>! IMPORTANT:</p> <p>If SNMP agent is disabled, all SNMP agent-related configurations will be removed.</p>
2. Configuring an SNMP view	<p>Optional.</p> <p>After creating SNMP views, you can specify an SNMP view for an SNMP group to limit the MIB objects that can be accessed by the SNMP group.</p>
3. Configuring an SNMP group	<p>Required.</p> <p>After creating an SNMP group, you can add SNMP users to the group when creating the users. Therefore, you can realize centralized management of users in the group through the management of the group.</p>
4. Configuring an SNMP user	<p>Required.</p> <p>Before creating an SNMP user, you need to create the SNMP group to which the user belongs.</p> <p>! IMPORTANT:</p> <p>After you change the local engine ID, the existing SNMPv3 users become invalid, and you must re-create the SNMPv3 users. For more information about engine ID, see "Enabling SNMP agent".</p>
5. Configuring the SNMP trap function	<p>Optional.</p> <p>Allows you to configure that the agent can send SNMP traps to the NMS, and configure information about the target host (usually the NMS) of the SNMP traps.</p> <p>The SNMP agent sends traps to inform the NMS of important events, such as a reboot.</p> <p>By default, an agent is allowed to send SNMP traps to the NMS.</p>
6. Displaying SNMP packet statistics	<p>Optional.</p>

2. Configure SNMP settings on the upper part of the page as described in [Table 33](#).
3. Click **Apply**.

Table 33 Configuration items

Item	Description
SNMP	Specify to enable or disable SNMP agent.
Local Engine ID	Configure the local engine ID. Validity of a user depends on the engine ID of the SNMP agent. If the engine ID when the user is created is not identical to the current engine ID, the user is invalid.
Maximum Packet Size	Configure the maximum size of an SNMP packet that the agent can receive/send.
Contact	Set a character string to describe the contact information for system maintenance. If the device is faulty, the maintainer can contact the manufacture factory according to the contact information of the device.
Location	Set a character string to describe the physical location of the device.
SNMP Version	Set the SNMP version run by the system.

Configuring an SNMP view

Perform the tasks in this section to configure an SNMP view.

Creating an SNMP view

1. Select **Device** > **SNMP** from the navigation tree.
2. Click the **View** tab.

The **View** tab appears.

SNMPv1/v2c configuration example

Network requirements

As shown in Figure 121, the NMS at 1.1.1.2/24 uses SNMPv1 or SNMPv2c to manage the switch (agent) at 1.1.1.1/24, and the switch automatically sends traps to report events to the NMS.

Figure 121 Network diagram

Configuring the agent

1. Enable SNMP:
 - a. Select **Device** > **SNMP** from the navigation tree.
The SNMP configuration page appears.
 - b. Select the **Enable** option, and select the **v1** and **v2c** options.
 - c. Set **Hewlett-Packard Development Company,L.P.** as the contact person, and **HP** as the physical location.
 - d. Click **Apply**.

Configuring the NMS

To avoid communication failures, make sure the NMS use the same SNMP settings as the agent.

To configure the NMS:

1. Configure the SNMP version for the NMS as v1 or v2c.
2. Create a read-only community and name it **public**.
3. Create a read and write community and name it **private**.

For information about how to configure the NMS, see the NMS manual.

Verifying the configuration

After the above configuration, an SNMP connection is established between the NMS and the agent. The NMS can get and configure the values of some parameters on the agent through MIB nodes.

Disable or enable an idle interface on the agent, and you can see the interface state change traps on the NMS.

SNMPv3 configuration example

Network requirements

As shown in [Figure 127](#), the NMS (1.1.1.2/24) uses SNMPv3 to monitor and manage the interface status of the AP (the agent) at 1.1.1.1/24, and the AP automatically sends traps to report events to the NMS.

The NMS and the agent perform authentication when they set up an SNMP session. The authentication algorithm is MD5 and the authentication key is **authkey**. The NMS and the AP also encrypt the SNMP packets between them by using the DES56 algorithm and the privacy key **prikey**.

Figure 127 Network diagram

Configuring the agent

1. Enable SNMP agent:
 - a. Select **Device > SNMP** from the navigation tree.
The SNMP configuration page appears.
 - b. Select the **Enable** option, and select the **v3** option.
 - c. Set **Hewlett-Packard Development Company,L.P.** as the contact person, and **HP** as the physical location.
 - d. Click **Apply**.

Configuring the NMS

To avoid communication failures, make sure the NMS use the same SNMP settings as the agent.

To configure the NMS:

1. Specify the SNMP version for the NMS as v3.
2. Create an SNMP user **user1**.
3. Enable both authentication and privacy functions
4. Use MD5 for authentication and DES56 for encryption.
5. Set the authentication key to **authkey** and the privacy key to **prikey**.

For information about configuring the NMS, see the NMS manual.

Verifying the configuration

After the above configuration, the NMS can establish an SNMP connection with the agent and query and reconfigure values of objects in the agent MIB.

Disable or enable an idle interface on the agent, and you can see the interface state change traps on the NMS.

Displaying interface statistics

Overview

The interface statistics module displays statistics about the packets received and sent through interfaces.

Configuration procedure

From the navigation tree, select **Device > Interface Statistics** to enter the interface statistics display page, as shown in [Figure 135](#). [Figure 814](#) describes the pages on the page.

Field	Description
OutErrors	Number of invalid packets sent through the interface

Configuring VLANs

Overview

Ethernet is a network technology based on the Carrier Sense Multiple Access/Collision Detect (CSMA/CD) mechanism. As the medium is shared, collisions and excessive broadcasts are common on an Ethernet. To address the issue, virtual LAN (VLAN) was introduced to break a LAN down into separate VLANs. VLANs are isolated from each other at Layer 2. A VLAN is a bridging domain, and all broadcast traffic is contained within it, as shown in [Figure 136](#).

Figure 136 A VLAN diagram

A VLAN is logically divided on an organizational basis rather than on a physical basis. For example, all workstations and servers used by a particular workgroup can be assigned to the same VLAN, regardless of their physical locations.

VLAN technology delivers the following benefits:

- Confining broadcast traffic within individual VLANs. This reduces bandwidth waste and improves network performance.
- Improving LAN security. By assigning user groups to different VLANs, you can isolate them at Layer 2. To enable communication between VLANs, routers or Layer 3 switches are required.
- Flexible virtual workgroup creation. As users from the same workgroup can be assigned to the same VLAN regardless of their physical locations, network construction and maintenance is much easier and more flexible.

VLAN fundamentals

To enable a network device to identify frames of different VLANs, a VLAN tag field is inserted into the data link layer encapsulation. The format of VLAN-tagged frames is defined in Institute of Electrical and Electronics Engineers (IEEE) 802.1Q-1999.

In the header of a traditional Ethernet data frame, the field after the destination MAC address and the source MAC address is the Type field indicating the upper layer protocol type, as shown in [Figure 137](#).

Figure 137 Traditional Ethernet frame format

IEEE 802.1Q inserts a four-byte VLAN tag after the DA&SA field, as shown in [Figure 138](#).

Figure 138 Position and format of VLAN tag

A VLAN tag comprises the following fields: tag protocol identifier (TPID), priority, canonical format indicator (CFI), and VLAN ID.

- **Tag protocol identifier (TPID)**—The 16-bit TPID field indicates whether the frame is VLAN-tagged and is 0x8100 by default.
- **Priority**—The 3-bit priority field indicates the 802.1p priority of the frame.
- **Canonical format indicator (CFI)**—The 1-bit CFI field specifies whether the MAC addresses are encapsulated in the standard format when packets are transmitted across different media. A value of 0 indicates that MAC addresses are encapsulated in the standard format. The value of 1 indicates that MAC addresses are encapsulated in a non-standard format. The value of the field is 0 by default.
- **VLAN ID**—The 12-bit VLAN ID field identifies the VLAN the frame belongs to. The VLAN ID range is 0 to 4095. Because 0 and 4095 are reserved, a VLAN ID actually ranges from 1 to 4094.

A network device handles an incoming frame depending on whether the frame is VLAN tagged and the value of the VLAN tag, if any.

The Ethernet II encapsulation format is used in this section. In addition to the Ethernet II encapsulation format, Ethernet also supports other encapsulation formats, including 802.2 LLC, 802.2 SNAP, and 802.3 raw. The VLAN tag fields are added to frames encapsulated in these formats for VLAN identification.

When a frame carrying multiple VLAN tags passes through, the device processes the frame according to its outer VLAN tag, and transmits the inner tags as payload.

VLAN types

You can implement VLANs based on the following criteria:

- Port
- MAC address
- Protocol
- IP subnet
- Policy
- Other criteria

The web interface is available only for port-based VLANs, and this chapter introduces only port-based VLANs.

Port-based VLAN

Port-based VLANs group VLAN members by port. A port forwards traffic for a VLAN only after it is assigned to the VLAN.

Port link type

You can configure the link type of a port as access, trunk, or hybrid. The link types use the following VLAN tag handling methods:

- **Access**—An access port can forward packets from only one specific VLAN and send these packets untagged. An access port can connect a terminal device that does not support VLAN packets or is used in scenarios that do not distinguish VLANs.
- **Trunk**—A trunk port can forward packets from multiple VLANs. Except packets from the port VLAN ID (PVID), packets sent out of a trunk port are VLAN-tagged. Ports connecting network devices are typically configured as trunk ports.
- **Hybrid**—A hybrid port can forward packets from multiple VLANs. A hybrid port allows traffic from some VLANs to pass through untagged and traffic from other VLANs to pass through tagged.

PVID

By default, VLAN 1 is the PVID for all ports. You can change the PVID for a port as required.

Follow these guidelines when you configure the PVID on a port:

- An access port can join only one VLAN. The VLAN to which the access port belongs is the PVID of the port.
- A trunk or hybrid port can join multiple VLANs, and you can configure a PVID for the port.
- You can use a nonexistent VLAN as the PVID for a hybrid or trunk port but not for an access port. After you delete the VLAN that an access port resides in, the PVID of the port changes to VLAN 1. Deleting the VLAN specified as the PVID of a trunk or hybrid port, however, does not affect the PVID setting on the port.
- Do not set the voice VLAN as the PVID of a port in automatic voice VLAN assignment mode. For information about voice VLAN, see "[Configuring a voice VLAN](#)."
- HP recommends that you set the same PVID for local and remote ports.
- Make sure that a port permits its PVID. Otherwise, when the port receives frames tagged with the PVID or untagged frames, the port drops these frames.

Frame handling methods

The following table shows how ports of different link types handle frames:

Actions	Access	Trunk	Hybrid
In the inbound direction for an untagged frame	Tags the frame with the PVID tag.	Checks whether the PVID is permitted on the port: <ul style="list-style-type: none">• If yes, tags the frame with the PVID tag.• If not, drops the frame.	
In the inbound direction for a tagged frame	<ul style="list-style-type: none">• Receives the frame if its VLAN ID is the same as the PVID.• Drops the frame if its VLAN ID is different from the PVID.	<ul style="list-style-type: none">• Receives the frame if its VLAN is permitted on the port.• Drops the frame if its VLAN is not permitted on the port.	

Actions	Access	Trunk	Hybrid
In the outbound direction	Removes the VLAN tag and sends the frame.	<ul style="list-style-type: none"> Removes the tag and sends the frame if the frame carries the PVID tag and the port belongs to the PVID. Sends the frame without removing the tag if its VLAN is carried on the port but is different from the PVID. 	Sends the frame if its VLAN is permitted on the port. The frame is sent with the VLAN tag removed or intact depending on your configuration with the port hybrid vlan command. This is true of the PVID.

Recommended VLAN configuration procedures

Assigning an access port to a VLAN

Step	Remarks
1. Creating VLANs	Required. Create one or multiple VLANs.
2. Configuring the link type of a port	Optional. Configure the link type of the port as access. By default, the link type of a port is access.
3. Setting the PVID for a port	Configure the PVID of the access port.
4. Configuring the access ports as untagged members of a VLAN	
a. Selecting VLANs Specify the range of VLANs available for selection during related operations. Configure a subset of all existing VLANs. This step is required before you perform operations on the Detail , Modify VLAN , and Modify Port tabs.	N/A
b. Modifying a VLAN Configure the access ports as untagged members of the specified VLAN.	Required. An access port has only one untagged VLAN and the untagged VLAN is its PVID. The three operations produce the same result, and the latest operation takes effect. By default, an access port is an untagged member of VLAN 1.
5. Modifying ports	Configure the untagged VLAN of the port.

Assigning a trunk port to a VLAN

Step	Remarks
1. Creating VLANs	Required. Create one or multiple VLANs.
2. Configuring the link type of a port	Optional. Configure the link type of the port as trunk. By default, the link type of a port is access.
3. Setting the PVID for a port	Configure the PVID of the trunk port. Required.
4. Configure the trunk port as an untagged member of the specified VLANs	A trunk port has only one untagged VLAN and the untagged VLAN is its PVID. The three operations produce the same result, and the latest operation takes effect. By default, the untagged VLAN of a trunk port is VLAN 1. NOTE:: When you change the untagged VLAN (PVID) of a trunk port, the former untagged VLAN automatically becomes a tagged VLAN of the trunk port.
a. Selecting VLANs Specify the range of VLANs available for selection during related operations. Configure a subset of all existing VLANs. This step is required before you perform operations on the Detail , Modify VLAN , and Modify Port tabs.	
b. Modifying a VLAN Configure the trunk port as an untagged member of the specified VLANs.	
5. Modifying ports	Configure the untagged VLAN of the trunk port.
6. Configure the trunk port as a tagged member of the specified VLANs	Required. A trunk port can have multiple tagged VLANs. You can repeat these steps to configure multiple tagged VLANs for the trunk port.
a. Selecting VLANs Specify the range of VLANs available for selection during related operations. Configure a subset of all existing VLANs. This step is required before you perform operations on the Detail , Modify VLAN , and Modify Port tabs.	
b. Modifying a VLAN Configure the trunk port as a tagged member of the specified VLANs.	
7. Modifying ports	Configure the tagged VLAN of the trunk port.

Assigning a hybrid port to a VLAN

Step	Remarks
1. Creating VLANs	Required. Create one or multiple VLANs.

Step	Remarks	
2. Configuring the link type of a port	Optional.	
	Configure the link type of the port as hybrid.	
	If you configure multiple untagged VLANs for a trunk port at the same time, the trunk port automatically becomes a hybrid port.	
3. Setting the PVID for a port	By default, the link type of a port is access.	
	Optional.	
	Configure the PVID of the hybrid port.	
4. Configure the hybrid port as an untagged member of the specified VLANs	By default, the PVID of a hybrid port is VLAN 1.	
	N/A	Required.
		A hybrid port can have multiple untagged VLANs. Repeat these steps to configure multiple untagged VLANs for a hybrid port.
5. Modifying ports	N/A	By default, the untagged VLAN of a hybrid port is VLAN 1.
		Configure the untagged VLAN of the hybrid port.
6. Configure the hybrid port as a tagged member of the specified VLAN		
	N/A	Required.
		A hybrid port can have multiple tagged VLANs. You can repeat these steps to configure multiple tagged VLANs for the hybrid port.
7. Modifying ports		
	Configure the tagged VLAN of the hybrid port.	

Creating VLANs

1. Select **Network** > **VLAN** from the navigation tree.
2. Click **Create** to enter the page for creating VLANs.
3. Enter the VLAN IDs, a VLAN ID range, or both.
4. Click **Create**.

By default, the description string of a VLAN is its VLAN ID, such as VLAN 0001.

Configuring the link type of a port

1. Select **Network > VLAN** from the navigation tree.
2. Click the **Modify Port** tab.
3. Select the port that you want to configure on the chassis front panel.
4. Select the **Link Type** option.
5. Set the link type, which can be access, hybrid, or trunk.
6. Click **Apply**.
A progress dialog box appears.
7. Click **Close** on the progress dialog box when the dialog box prompts that the configuration succeeds.

Figure 140 Modifying ports

The screenshot shows the 'Modify Port' configuration page. At the top, there is a navigation bar with tabs: 'Select VLAN', 'Create', 'Port Detail', 'Detail', 'Modify VLAN', 'Modify Port' (which is active), and 'Remove'. Below the navigation bar, the 'Select Ports' section displays a diagram of a switch chassis with 9 ports. Ports 1 through 8 are highlighted in blue, indicating they are selected. Port 9 is not highlighted. To the right of the port diagram, the text 'HP 1910-8G-PoE+...' is visible. Below the port diagram, there are two buttons: 'Select All' and 'Select None'. To the right of these buttons, there is a small black square icon and the text 'Not available for selection'. Below the 'Select Ports' section, the 'Select membership type:' section contains five radio buttons: 'Untagged', 'Tagged', 'Not A Member', 'Link Type' (which is selected), and 'PVID'. Below the radio buttons, the 'Link Type' dropdown menu is set to 'Access'. Below the 'Link Type' dropdown, the 'Selected ports:' section contains a text box with the text 'Link Type' and 'GE1/0/1-GE1/0/4'. At the bottom right of the page, there are two buttons: 'Apply' and 'Cancel'.

You can also configure the link type of a port on the **Setup** tab of **Device > Port Management**. For more information, see "[Managing ports](#)."

Setting the PVID for a port

1. Select **Network > VLAN** from the navigation tree.
2. Click the **Modify Port** tab.
3. Select the port that you want to configure on the chassis front panel.
4. Select the **PVID** option.
The option allows you to modify the PVID of the port.
5. Set a PVID for the port. By selecting the **Delete** box, you can restore the PVID of the port to the default, which is VLAN 1.
The PVID of an access port must be an existing VLAN.
6. Click **Apply**.
A progress dialog box appears.
7. Click **Close** on the progress dialog box when the dialog box prompts that the configuration succeeds.

VLAN configuration example

Network requirements

As shown in [Figure 145](#), trunk port GigabitEthernet 1/0/1 of Switch A is connected to trunk port GigabitEthernet 1/0/1 of Switch B.

Configure the PVID of GigabitEthernet 1/0/1 as VLAN 100, and configure GigabitEthernet 1/0/1 to permit packets of VLAN 2, VLAN 6 through VLAN 50, and VLAN 100 to pass through.

Figure 145 Network diagram

Configuring Switch A

1. Configure GigabitEthernet 1/0/1 as a trunk port and configure VLAN 100 as the PVID:
 - a. Select **Device > Port Management** from the navigation tree.
 - b. Click **Setup** to enter the page for setting ports.
 - c. Select **Trunk** in the **Link Type** list, select the **PVID** box, and then enter PVID 100.
 - d. Select GigabitEthernet 1/0/1 on the chassis front device panel.
 - e. Click **Apply**.

Figure 146 Configuring GigabitEthernet 1/0/1 as a trunk port and its PVID as 100

Figure 150 Assigning GigabitEthernet 1/0/1 to VLAN 2 and to VLANs 6 through 50 as a tagged member

The screenshot shows a web-based configuration interface for a network switch. At the top, there is a navigation bar with tabs: 'Select VLAN', 'Create', 'Port Detail', 'Detail', 'Modify VLAN', 'Modify Port' (which is active), and 'Remove'. Below the navigation bar, the 'Select Ports' section displays a port selection interface for an 'HP 1910-8G-PoE+...' switch. A grid of port numbers (1-9) is shown, with port 1 highlighted. Below the grid are 'Select All' and 'Select None' buttons. A 'Not available for selection' message is also present. The 'Select membership type:' section has five radio buttons: 'Untagged', 'Tagged' (which is selected), 'Not A Member', 'Link Type', and 'PVID'. The 'Enter VLAN IDs to which the port is to be assigned:' section contains a text input field with '2, 6-50' and an example '1,3,5-10'. The 'Selected ports:' section shows a list with 'Tagged Membership' and 'GE1/0/1'. At the bottom right, there are 'Apply' and 'Cancel' buttons.

Configuring Switch B

Configure Switch B in the same way Switch A is configured.

Configuration guidelines

Follow these guidelines when you configure VLANs:

- As the default VLAN, VLAN 1 can be neither created nor removed manually.
- You cannot manually create or remove VLANs reserved for special purposes.
- Dynamic VLANs cannot be removed on the page for removing VLANs.

Configuring VLAN interfaces

Overview

For hosts of different VLANs to communicate at Layer 3, you can use VLAN interfaces. VLAN interfaces are virtual interfaces used for Layer 3 communication between different VLANs. They do not exist as physical entities on devices. For each VLAN, you can create one VLAN interface. You can assign the VLAN interface an IP address and specify the IP address as the gateway address for the devices in the VLAN, so that traffic can be routed to other IP subnets.

Creating a VLAN interface

IMPORTANT:

Before creating a VLAN interface, you must create the corresponding VLAN in **Network > VLAN**. For more information, see "[Configuring VLANs](#)."

When creating a VLAN interface, you can select to assign an IPv4 address and an IPv6 link-local address to the VLAN interface in this step or in a separate step. If you do not select to configure an IP address, you can create the VLAN interface, and configure an IP address for the VLAN interface by modifying it.

To create a VLAN interface:

1. Select **Network > VLAN Interface** from the navigation tree.
2. Click **Create** to enter the page for creating a VLAN interface.

Figure 151 Creating a VLAN interface

Summary	Create	Modify	Remove

4. Click **Apply**.

Table 43 Configuration items

Item	Description	
Input a VLAN ID:	Enter the ID of the VLAN interface to be created. Before creating a VLAN interface, make sure that the corresponding VLAN exists.	
Configure Primary IPv4 Address	DHCP	Configure the way in which the VLAN interface gets an IPv4 address.
	BOOTP	Allow the VLAN interface to obtain an IP address automatically by selecting the DHCP or BOOTP option, or manually assign the VLAN interface an IP address by selecting the Manual option.
	Manual	
	IPv4 Address	Configure an IPv4 address for the VLAN interface. This field is available after you select the Manual option.
	Mask Length	Set the subnet mask length (or enter a mask in dotted decimal notation format). This field is available after you select the Manual option.

These items are available after you select the **Configure Primary IPv4 Address** box.

Item	Description	
Configure IPv6 Link Local Address	Auto	Configure the way in which the VLAN interface obtains an IPv6 link-local address.
	Select the Auto or Manual option:	
	Manual	<ul style="list-style-type: none"> Auto—The device automatically assigns a link-local address for the VLAN interface based on the link-local address prefix (FE80::/64) and the link-layer address of the VLAN interface.
		<ul style="list-style-type: none"> Manual—Requires manual assignment.
IPv6 Address	Configure an IPv6 link-local address for the VLAN interface.	
	This field is available after you select the Manual option. The prefix of the IPv6 link-local address you enter must be FE80::/64.	

These items are available after you select the **Configure IPv6 Link Local Address** box.

Modifying a VLAN interface

By modifying a VLAN interface, you can assign an IPv4 address, an IPv6 link-local address, and an IPv6 site-local address, or global unicast address to the VLAN interface, and shut down or bring up the VLAN interface.

To modify a VLAN interface:

1. Select **Network > VLAN Interface** from the navigation tree.
2. Click the **Modify** tab to enter the page for modifying a VLAN interface.

Figure 152 Modifying a VLAN interface

The screenshot displays the 'Modify' tab for a VLAN interface configuration. At the top, there are tabs for 'Summary', 'Create', 'Modify' (selected), and 'Remove'. Below the tabs, a dropdown menu shows 'Select VLAN Interface' with '1' selected. The main configuration area is divided into two columns. The left column, titled 'Modify IPv4 Address', includes a sub-section 'Modify Primary IP And Status' with radio buttons for 'DHCP', 'BOOTP', and 'Manual' (selected). Below these are input fields for the IP address (192.168.0.96) and the netmask (255.255.255.0). An 'Admin Status' dropdown is set to 'Up', and an 'Apply' button is at the bottom right. The right column, titled 'Modify IPv6 Address', includes a sub-section 'Modify IPv6 Link Local Address And Status' with radio buttons for 'Auto' (selected) and 'Manual'. Below this is an empty input field. An 'Admin Status' dropdown is set to 'Up', and an 'Apply' button is at the bottom right. Further down, a section titled 'Add IPv6 Unicast Address' has an input field for the address (64) and a checkbox for 'EUI-64'. An 'Apply' button is at the bottom right. At the very bottom, there is a section titled 'IPv6 Address' with an empty input field.

3. Modify a VLAN interface as described in [Table 44](#).
4. Click **Apply**.

Table 44 Configuration items

Item	Description
Select VLAN Interface	<p>Select the VLAN interface to be configured.</p> <p>The VLAN interfaces available for selection in the list are those created on the page for creating VLAN interfaces.</p>
Modify IPv4 Address	DHCP
	BOOTP
	Manual
	Admin Status

- Configure the way in which the VLAN interface gets an IPv4 address.
- Allow the VLAN interface to obtain an IP address automatically by selecting the **DHCP** or **BOOTP** option, or manually assign the VLAN interface an IP address by selecting the **Manual** option. In the latter case, you need to set the mask length or enter a mask in dotted decimal notation format.
- Select **Up** or **Down** in the **Admin Status** list to bring up or shut down the selected VLAN interface.
- When the VLAN interface fails, you can shut down and then bring up the VLAN interface, which might restore the VLAN interface.
- By default, a VLAN interface is down if all Ethernet ports in the VLAN are down; otherwise, the VLAN interface is up.
- NOTE:**
- The current VLAN interface state in the **Modify IPv4 Address** and **Modify IPv6 Address** frames changes as the VLAN interface state is modified in the **Admin Status** list.
 - The state of each port in the VLAN is independent of the VLAN interface state.

Item	Description
Modify IPv6 Address	<p>Auto</p> <p>Configure the way in which the VLAN interface obtains an IPv6 link-local address.</p> <p>Select the Auto or Manual option:</p> <ul style="list-style-type: none"> Auto—The device automatically assigns a link-local address for the VLAN interface according to the link-local address prefix (FE80::/64) and the link-layer address of the VLAN interface. Manual—Configures an IPv6 link-local address for the VLAN interface manually.
	<p>Manual</p> <p>Select Up or Down in the Admin Status list to bring up or shut down the selected VLAN interface.</p> <p>When the VLAN interface fails, you can shut down and then enable the VLAN interface, which might restore the VLAN interface.</p> <p>By default, a VLAN interface is down if all Ethernet ports in the VLAN are down; otherwise, the VLAN interface is up.</p> <p>NOTE:</p> <ul style="list-style-type: none"> The current VLAN interface state in the Modify IPv4 Address and Modify IPv6 Address frames changes as the VLAN interface state is modified in the Admin Status list. The state of each port in the VLAN is independent of the VLAN interface state.
	<p>Admin Status</p> <p>Assign an IPv6 site-local address or global unicast address to the VLAN interface.</p>
	<p>Add IPv6 Unicast Address</p> <p>Enter an IPv6 address in the field and select a prefix length in the list next to it.</p> <p>The prefix of the IPv6 address you entered cannot be FE80::/10, the prefix of the link-local address.</p> <p>The prefix of the IPv6 site-local address you enter must be FEC0::/10.</p>
	<p>EUI-64</p> <p>Specify to generate IPv6 site-local addresses or global unicast addresses in the EUI-64 format.</p> <p>If the EUI-64 box is not specified, manually configured IPv6 site-local addresses or global unicast addresses are used.</p>

After you modify the IPv4 address and status or the IPv6 address and status, or add an IPv6 unicast address for a selected VLAN interface on the page for modifying VLAN interfaces, you must click the correct **Apply** button to submit the modification.

After you change the IP address of the VLAN interface you are using to log in to the device, you will be disconnected from the device. You can use the changed IP address to re-log in.

Configuration guidelines

When you configure VLAN interfaces, follow these guidelines:

- A link-local address is automatically generated for an IPv6 VLAN interface after an IPv6 site-local address or global unicast address is configured for the VLAN interface. This generated link-local address is the same as the one generated in the **Auto** mode. If a manually assigned link-local address is available, the manually assigned one takes effect. After the manually assigned link-local address is removed, the automatically generated one takes effect.
- For an IPv6 VLAN interface whose IPv6 link-local address is generated automatically after you assign an IPv6 site-local address or global unicast address, removing the IPv6 site-local address or global unicast address also removes the generated IPv6 link-local address.

- For IPv6 link-local address configuration, manual assignment takes precedence over automatic generation. If you first adopt the manual assignment and then the automatic generation, the automatically generated link-local address will not take effect and the link-local address of the interface is still the manually assigned one. But if you remove the manually assigned one, the one automatically generated takes effect.

Configuring a voice VLAN

Overview

The voice technology is developing quickly, and more and more voice devices are in use. In broadband communities, data traffic and voice traffic are usually transmitted in the network at the same time. Usually, voice traffic needs higher priority than data traffic to reduce the transmission delay and packet loss ratio.

A voice VLAN is configured for voice traffic. After assigning the ports that connect to voice devices to a voice VLAN, the system automatically modifies quality of service (QoS) parameters for voice traffic, to improve the transmission priority of voice traffic and ensure voice quality.

Common voice devices include IP phones and integrated access devices (IADs). Only IP phones are used in the voice VLAN configuration examples in this document.

OUI addresses

A device determines whether an incoming packet is a voice packet by checking its source MAC address. If the source MAC address of a received packet matches an organizationally unique identifier (OUI) in the voice device OUI list (referred to as the OUI list in this document) maintained by the switch, the packet is regarded as a voice packet.

You can add OUI addresses to the OUI list maintained by the device or use the default OUI list shown in [Table 45](#) for voice traffic identification.

Table 45 The default OUI list

Number	OUI Address	Vendor
1	0001-e300-0000	Siemens phone
2	0003-6b00-0000	Cisco phone
3	0004-0d00-0000	Avaya phone
4	00d0-1e00-0000	Pingtel phone
5	0060-b900-0000	Philips/NEC phone
6	00e0-7500-0000	Polycom phone
7	00e0-bb00-0000	3Com phone

An OUI address is usually the first 24 bits of a MAC address (in binary format). It is a globally unique identifier assigned to a vendor by the IEEE. In this document, however, OUI addresses are used by the system to determine whether received packets are voice packets and they are the results of the AND operation of a MAC address and a mask. For more information, see "[Adding OUI addresses to the OUI list.](#)"

You can remove default OUI addresses and if needed, add them to the OUI list after their removal.

Voice VLAN assignment modes

A port connected to a voice device, an IP phone for example, can be assigned to a voice VLAN in one of the following modes:

- **Automatic mode**—The system matches the source MAC addresses in the protocol packets (untagged packets) sent by the IP phone upon its power-on against the OUI list. If a match is found, the system automatically assigns the receiving port to a voice VLAN, issues ACL rules and configures the packet precedence. You can configure an aging timer for the voice VLAN. The system will remove the port from the voice VLAN when the aging timer expires if no voice packet is received on the port during the aging timer. The system automatically assigns ports to, or removes ports from, a voice VLAN. Automatic mode is suitable for scenarios where PCs and IP phones connected in series access the network through the device and ports on the device simultaneously transmit both voice traffic and data traffic, as shown in [Figure 153](#). When the voice VLAN works correctly, if the system reboots, the system reassigns ports in automatic voice VLAN assignment mode to the voice VLAN after the reboot, making sure existing voice connections can work correctly. In this case, voice traffic streams do not trigger port assignment to the voice VLAN.

Figure 153 PCs and IP phones connected in series access the network

- **Manual mode**—You must assign the port to a voice VLAN manually. Then, the system matches the source MAC addresses in the packets against the OUI addresses. If a match is found, the system issues ACL rules and configures the packet precedence. In this mode, you must manually assign ports to, or remove ports from, a voice VLAN. Manual mode is suitable for scenarios where only IP phones access the network through the device, and ports on the device transmit only voice traffic, as shown in [Figure 154](#). In this mode, ports assigned to a voice VLAN transmit voice traffic exclusively, which prevents the impact of data traffic on the transmission of voice traffic.

Figure 154 Only IP phones access the network

Both modes forward tagged packets according to their tags.

[Table 46](#) and [Table 47](#) list the configurations required for ports of different link types to support tagged or untagged voice traffic sent from IP phones when different voice VLAN assignment modes are configured.

- IP phones send tagged voice traffic

Table 46 Required configurations on ports of different link types for them to support tagged voice traffic

Port link type	Voice VLAN assignment mode supported for tagged voice traffic	Configuration requirements
Access	N/A	N/A
Trunk	Automatic and manual	In automatic mode, the PVID of the port cannot be the voice VLAN. In manual mode, the PVID of the port cannot be the voice VLAN. Configure the port to permit packets of the voice VLAN to pass through.
Hybrid	Automatic and manual	In automatic mode, the PVID of the port cannot be the voice VLAN. In manual mode, the PVID of the port cannot be the voice VLAN. Configure the port to permit packets of the voice VLAN to pass through tagged.

- IP phones send untagged voice traffic

When IP phones send untagged voice traffic, you can only configure the voice traffic receiving ports on the device to operate in manual voice VLAN assignment mode.

Table 47 Required configurations on ports of different link types for them to support tagged voice traffic

Port link type	Voice VLAN assignment mode supported for untagged voice traffic	Configuration requirements
Access	Manual	Configure the PVID of the port as the voice VLAN.
Trunk	Manual	Configure the PVID of the port as the voice VLAN and assign the port to the voice VLAN.
Hybrid	Manual	Configure the PVID of the port as the voice VLAN and configure the port to permit packets of the voice VLAN to pass through untagged.

If an IP phone sends tagged voice traffic and its access port is configured with 802.1X authentication and guest VLAN, you must assign different VLAN IDs for the voice VLAN, the PVID of the access port, and the 802.1X guest VLAN for the functions to operate correctly.

If an IP phone sends untagged voice traffic, to deliver the voice VLAN function, you must configure the PVID of the access port as the voice VLAN. As a result, 802.1X authentication does not take effect.

Security mode and normal mode of voice VLANs

Depending on their inbound packet filtering mechanisms, voice VLAN-enabled ports operate in one of the following modes:

- **Normal mode**—In this mode, both voice packets and non-voice packets are allowed to pass through a voice VLAN-enabled inbound port. When receiving a voice packet, the port forwards it without checking its source MAC address against the OUI addresses configured for the device. If the PVID of the port is the voice VLAN and the port operates in manual VLAN assignment mode, the port forwards all received untagged packets in the voice VLAN. In normal mode, the voice VLANs are vulnerable to traffic attacks. Vicious users can forge a large amount of untagged packets and send them to voice VLAN-enabled ports to consume the voice VLAN bandwidth, affecting normal voice communication.
- **Security mode**—In this mode, only voice packets whose source MAC addresses comply with the recognizable OUI addresses can pass through the voice VLAN-enabled inbound port, but all other packets are dropped.

In a safe network, you can configure the voice VLANs to operate in normal mode, reducing the consumption of system resources due to source MAC addresses checking.

HP recommends not transmitting both voice packets and non-voice packets in a voice VLAN. If you have to, first make sure that the voice VLAN security mode is disabled.

Table 48 How a voice VLAN-enable port processes packets in security/normal mode

Voice VLAN operating mode	Packet type	Packet processing mode
Security mode	Untagged packets	If the source MAC address of a packet matches an OUI address configured for the device, it is forwarded in the voice VLAN; otherwise, it is dropped.
	Packets carrying the voice VLAN tag	
	Packets carrying other tags	Forwarded or dropped depending on whether the port allows packets of these VLANs to pass through
Normal mode	Untagged packets	The port does not check the source MAC addresses of inbound packets. All types of packets can be transmitted in the voice VLAN.
	Packets carrying the voice VLAN tag	
	Packets carrying other tags	Forwarded or dropped depending on whether the port allows packets of these VLANs to pass through

Recommended voice VLAN configuration procedure

Before configuring the voice VLAN, you must create the VLAN and configure the link type of each port to be assigned to the VLAN. Because VLAN 1 is the system-default VLAN, you do not need to create it; however, you cannot configure it as the voice VLAN. For information about port link types, see "[Managing ports](#)."

Recommended configuration procedure for a port in automatic voice VLAN assignment mode

Step	Remarks
1. Configuring voice VLAN globally	(Optional.) Configure the voice VLAN to operate in security mode and configure the aging timer
2. Configuring voice VLAN on ports	(Required.) Configure the voice VLAN assignment mode of a port as automatic and enable the voice VLAN function on the port. By default, the voice VLAN assignment mode of a port is automatic, and the voice VLAN function is disabled on a port.
3. Adding OUI addresses to the OUI list	(Optional.) The system supports up to 128 OUI addresses. By default, the system is configured with seven OUI addresses, as shown in Table 45 .

Recommended configuration procedure for a port in manual voice VLAN assignment mode

Step	Remarks
1. Configuring voice VLAN globally	(Optional.) Configure the voice VLAN to operate in security mode and configure the aging timer.
2. Assigning the port to the voice VLAN	(Required.) After an access port is assigned to the voice VLAN, the voice VLAN automatically becomes the PVID of the access port. For more information, see " Configuring VLANs ."
3. Configuring the voice VLAN as the PVID of a hybrid or trunk port	(Optional.) This task is required if the incoming voice traffic is untagged and the link type of the receiving port is trunk or hybrid. If the incoming voice traffic is tagged, do not perform this task. For more information, see " Managing ports ."
4. Configuring voice VLAN on ports	(Required.) Configure the voice VLAN assignment mode of a port as manual and enable voice VLAN on the port. By default, the voice VLAN assignment mode of a port is automatic, and voice VLAN is disabled on a port.
5. Adding OUI addresses to the OUI list	(Optional.) You can configure up to 128 OUI addresses. By default, the system is configured with the seven OUI addresses shown in Table 45 .

Configuring voice VLAN globally

1. Select **Network > Voice VLAN** from the navigation tree.

- Click the **Setup** tab.

Figure 155 Configuring voice VLAN

Summary	Setup	Port Setup	OUI Summary	OUI Add	OUI Remove
---------	-------	------------	-------------	---------	------------

Voice VLAN security: ▾

Voice VLAN aging time: *minutes (5-43200, Default = 1440)

Items marked with an asterisk(*) are required

- Configure the global voice VLAN settings as described in [Table 49](#).

- Click **Apply**.

Table 49 Configuration items

Item	Description
Voice VLAN security	Select Enable or Disable in the list to enable or disable the voice VLAN security mode. By default, the voice VLANs operate in security mode.
Voice VLAN aging time	Set the voice VLAN aging timer. The voice VLAN aging timer setting only applies to a port in automatic voice VLAN assignment mode. The voice VLAN aging timer starts as soon as the port is assigned to the voice VLAN. If no voice packet has been received before the timer expires, the port is removed from the voice VLAN.

Configuring voice VLAN on ports

- Select **Network > Voice VLAN** from the navigation tree.
- Click the **Port Setup** tab.

Figure 156 Configuring voice VLAN on ports

2. Configure GigabitEthernet 1/0/1 as a hybrid port and configure its PVID as VLAN 2:
 - a. Select **Device > Port Management** from the navigation tree.

- b. Click the **Setup** tab.
- c. Select **Hybrid** from the **Link Type** list.
- d. Select the **PVID** box and enter 2 in the field.
- e. Select GigabitEthernet 1/0/1 from the chassis front panel.
- f. Click **Apply**.

3. Assign GigabitEthernet 1/0/1 to VLAN 2 as an untagged member:
 - a. Select **Network > VLAN** from the navigation tree.
 - b. Click the **Modify Port** tab.
 - c. Select GigabitEthernet 1/0/1 from the chassis front panel.
 - d. Select the **Untagged** option.
 - e. Enter VLAN ID 2.
 - f. Click **Apply**.

A configuration progress dialog box appears.
 - g. After the configuration process is complete, click **Close**.

Figure 169 Assigning GigabitEthernet 1/0/1 to VLAN 2 as an untagged member

The screenshot displays a network configuration interface with the following elements:

- Navigation Tabs:** Select VLAN, Create, Port Detail, Detail, Modify VLAN, Modify Port (highlighted), and Remove.
- Select Ports Section:** A visual representation of a switch front panel with ports 1 through 9. Port 1 is highlighted with a red box. Below the panel are 'Select All' and 'Select None' buttons. A 'Not available for selection' message is shown next to a disabled port icon.
- Select membership type:** Radio buttons for 'Untagged' (selected and highlighted with a red box), 'Tagged', 'Not A Member', 'Link Type', and 'PVID'.
- Enter VLAN IDs to which the port is to be assigned:** A text field labeled 'VLAN IDs:' containing the value '2' (highlighted with a red box). An example 'Example: 1,3,5-10' is provided.
- Selected ports:** A list box showing 'Untagged Membership' and 'GE 1/0/1' (highlighted with a red box).
- Buttons:** 'Apply' (highlighted with a red box) and 'Cancel' buttons at the bottom right.

4. Configure voice VLAN on GigabitEthernet 1/0/1:
 - a. Select **Network** > **Voice VLAN** from the navigation tree.
 - b. Click the **Port Setup** tab.
 - c. Select **Manual** in the **Voice VLAN port mode** list.
 - d. Select **Enable** in the **Voice VLAN port state** list.
 - e. Enter 2 in the **VLAN IDs** field.
 - f. Select GigabitEthernet 1/0/1 on the chassis front panel.
 - g. Click **Apply**.

Configuration guidelines

When you configure the voice VLAN function, follow these guidelines:

- To remove a VLAN functioning as a voice VLAN, disable its voice VLAN function first.
- Only one VLAN is supported and only an existing static VLAN can be configured as the voice VLAN.
- Do not enable the voice VLAN function on a link aggregation group member port.
- After you assign a port operating in manual voice VLAN assignment mode to the voice VLAN, the voice VLAN takes effect.

Configuring MAC address tables

MAC address configurations related to interfaces apply only to Layer 2 Ethernet interfaces.

This document covers only the management of unicast MAC address entries, including static, dynamic, and blackhole MAC address entries.

Overview

To reduce single-destination packet floodings in a switched LAN, an Ethernet device uses a MAC address table to forward frames. This table describes from which port a MAC address (or host) can be reached. Upon receiving a frame, the device uses the destination MAC address of the frame to look for a match in the MAC address table. If a match is found, the device forwards the frame out of the outgoing interface in the matching entry. If no match is found, the device floods the frame out of all but the incoming port.

How a MAC address table entry is created

The device automatically learns entries in the MAC address table, or you can add them manually.

MAC address learning

The device can automatically populate its MAC address table by learning the source MAC addresses of incoming frames on each port.

When a frame arrives at a port (for example, Port A), the device performs the following tasks:

1. Verifies the source MAC address (for example, MAC-SOURCE) of the frame.
2. Looks up the source MAC address in the MAC address table.
 - If an entry is found, the device updates the entry.
 - If no entry is found, the device adds an entry for MAC-SOURCE and Port A.
3. When the device receives a frame destined for MAC-SOURCE after learning this source MAC address, the device finds the MAC-SOURCE entry in the MAC address table and forwards the frame out of Port A.

The device performs this learning process each time it receives a frame from an unknown source MAC address, until the MAC address table is fully populated.

Manually configuring MAC address entries

With dynamic MAC address learning, a device does not distinguish between illegitimate and legitimate frames. For example, when a hacker sends frames with a forged source MAC address to a port different from the one with which the real MAC address is associated, the device creates an entry for the forged MAC address, and forwards frames destined for the legal user to the hacker instead.

To improve port security, you can manually add MAC address entries to the MAC address table of the device to bind specific user devices to the port.

Types of MAC address table entries

A MAC address table can contain the following types of entries:

- **Static entries**—Manually added and never age out.
- **Dynamic entries**—Manually added or dynamically learned, and might age out.
- **Blackhole entries**—Manually configured and never age out. Blackhole entries are configured for filtering out frames with specific source or destination MAC addresses. For example, to block all frames destined for a specific user for security concerns, you can configure the MAC address of this user as a blackhole MAC address entry.

A static or blackhole MAC address entry can overwrite a dynamic MAC address entry, but not vice versa.

To adapt to network changes and prevent inactive entries from occupying table space, an aging mechanism is adopted for dynamic MAC address entries. Each time a dynamic MAC address entry is learned or created, an aging timer starts. If the entry has not updated when the aging timer expires, the device deletes the entry. If the entry has updated before the aging timer expires, the aging timer restarts.

Displaying and configuring MAC address entries

1. Select **Network > MAC** from the navigation tree.

The **MAC** tab automatically appears, which shows all the MAC address entries on the device, as shown in Figure 174.

Figure 174 The MAC tab

Setting the aging time of MAC address entries

1. Select **Network > MAC** from the navigation tree.
2. Click the **Setup** tab to enter the page for setting the MAC address entry aging time, as shown in [Figure 176](#).

Figure 176 Setting the aging time for MAC address entries

The screenshot shows a web interface for configuring MAC address entries. At the top, there are two tabs: 'MAC' and 'Setup', with 'Setup' being the active tab. Below the tabs, the heading 'Set mac-address aging time' is displayed. There are two radio button options: 'No-aging' and 'Aging Time'. The 'Aging Time' option is selected. To the right of the 'Aging Time' radio button is a text input field containing the value '300'. To the right of the input field is the text 'seconds(10-630, Default = 300)'. At the bottom right of the configuration area is an 'Apply' button.

3. Configure the aging time for MAC address entries as described in Table 53.
4. Click **Apply**.

Table 53 Configuration items

MAC address configuration example

Network requirements

Use the Web-based NMS to configure the MAC address table of the device. Add a static MAC address 00e0-fc35-dc71 under GigabitEthernet 1/0/1 in VLAN 1.

Creating a static MAC address entry

1. Select **Network** > **MAC** from the navigation tree.
By default, the **MAC** tab is displayed.
2. Click **Add**.
The page shown in Figure 177 appears.
3. Configure a MAC address entry:
 - a. Enter MAC address **00e0-fc35-dc71**.
 - b. Select **static** from the **Type** list.
 - c. Select **1** from the **VLAN** list.
 - d. Select **GigabitEthernet1/0/1** from the **Port** list.
4. Click **Apply**.

Configuring MSTP

As a Layer 2 management protocol, the Spanning Tree Protocol (STP) eliminates Layer 2 loops by selectively blocking redundant links in a network, and in the mean time, allows for link redundancy.

Like many other protocols, STP evolves as the network grows. The later versions of STP are Rapid Spanning Tree Protocol (RSTP) and Multiple Spanning Tree Protocol (MSTP). This chapter describes the characteristics of STP, RSTP, and MSTP.

STP

STP was developed based on the 802.1d standard of IEEE to eliminate loops at the data link layer in a local area network (LAN). Devices running this protocol detect loops in the network by exchanging information with one another and eliminate loops by selectively blocking certain ports to prune the loop structure into a loop-free tree structure. This avoids proliferation and infinite cycling of packets that would occur in a loop network and prevents decreased performance of network devices caused by duplicate packets received.

In the narrow sense, STP refers to the IEEE 802.1d STP; in the broad sense, STP refers to the IEEE 802.1d STP and various enhanced spanning tree protocols derived from that protocol.

STP protocol packets

STP uses bridge protocol data units (BPDUs), also known as configuration messages, as its protocol packets.

STP-enabled network devices exchange BPDUs to establish a spanning tree. BPDUs contain sufficient information for the network devices to complete spanning tree calculation.

In STP, BPDUs have the following types:

- **Configuration BPDUs**—Used for calculating a spanning tree and maintaining the spanning tree topology.
- **Topology change notification (TCN) BPDUs**—Used for notifying the concerned devices of network topology changes, if any.

Basic concepts in STP

Root bridge

A tree network must have a root bridge. The entire network contains only one root bridge, and all the other bridges in the network are called "leaf nodes". The root bridge is not permanent, but can change with changes of the network topology.

Upon initialization of a network, each device generates and periodically sends configuration BPDUs, with itself as the root bridge. After network convergence, only the root bridge generates and periodically sends configuration BPDUs. The other devices only forward the BPDUs.

Root port

On a non-root bridge, the port nearest to the root bridge is the root port. The root port communicates with the root bridge. Each non-root bridge has only one root port. The root bridge has no root port.

Designated bridge and designated port

Classification	Designated bridge	Designated port
For a device	A device directly connected to the local device and responsible for forwarding BPDUs to the local device.	The port through which the designated bridge forwards BPDUs to the local device.
For a LAN	The device responsible for forwarding BPDUs to this LAN segment.	The port through which the designated bridge forwards BPDUs to this LAN segment.

As shown in Figure 178, Device B and Device C are connected to the LAN. AP1 and AP2, BP1 and BP2, and CP1 and CP2 are ports on Device A, Device B, and Device C, respectively.

- If Device A forwards BPDUs to Device B through AP1, the designated bridge for Device B is Device A, and the designated port of Device B is port AP1 on Device A.
- If Device B forwards BPDUs to the LAN, the designated bridge for the LAN is Device B, and the designated port for the LAN is the port BP2 on Device B.

Figure 178 Designated bridges and designated ports

NOTE:

All the ports on the root bridge are designated ports.

Path cost

Path cost is a reference value used for link selection in STP. STP calculates path costs to select the most robust links and block redundant links that are less robust, to prune the network into a loop-free tree.

How STP works

The devices on a network exchange BPDUs to identify the network topology. Configuration BPDUs contain sufficient information for the network devices to complete spanning tree calculation. A configuration BPDU includes the following important fields:

- **Root bridge ID**—Consisting of the priority and MAC address of the root bridge.
- **Root path cost**—Cost of the path to the root bridge.
- **Designated bridge ID**—Consisting of the priority and MAC address of the designated bridge.
- **Designated port ID**—Designated port priority plus port name.
- **Message age**—Age of the configuration BPDU while it propagates in the network.
- **Max age**—Maximum age of the configuration BPDU can be maintained on a device.
- **Hello time**—Configuration BPDU interval.
- **Forward delay**—Delay used by STP bridges to transit the state of the root and designated ports to forwarding.

The descriptions and examples in this document involve only the following fields in the configuration BPDUs:

- Root bridge ID (represented by device priority).
- Root path cost.
- Designated bridge ID (represented by device priority).
- Designated port ID (represented by port name).

Calculation process of the STP algorithm

The spanning tree calculation process described in the following sections is a simplified process for example only.

The STP algorithm uses the following calculation process:

1. State initialization.

Upon initialization of a device, each port generates a BPDU with the port as the designated port, the device as the root bridge, 0 as the root path cost, and the device ID as the designated bridge ID.

2. Root bridge selection.

Initially, each STP-enabled device on the network assumes itself to be the root bridge, with its own device ID as the root bridge ID. By exchanging configuration BPDUs, the devices compare their root bridge IDs to elect the device with the smallest root bridge ID as the root bridge.

3. Root port and designated ports selection on the non-root bridges.

Table 54 Selecting the root port and designated ports

Step	Description
1	A non-root-bridge device regards the port on which it received the optimum configuration BPDU as the root port. Table 55 describes how the optimum configuration BPDU is selected.
2	Based on the configuration BPDU and the path cost of the root port, the device calculates a designated port configuration BPDU for each of the other ports. <ul style="list-style-type: none"> • The root bridge ID is replaced with that of the configuration BPDU of the root port. • The root path cost is replaced with that of the configuration BPDU of the root port plus the path cost of the root port. • The designated bridge ID is replaced with the ID of this device. • The designated port ID is replaced with the ID of this port.

Step	Description
3	<p>The device compares the calculated configuration BPDU with the configuration BPDU on the port of which the port role is to be defined, and acts depending on the comparison result:</p> <ul style="list-style-type: none"> • If the calculated configuration BPDU is superior, the device considers this port as the designated port, and replaces the configuration BPDU on the port with the calculated configuration BPDU, which will be sent out periodically. • If the configuration BPDU on the port is superior, the device blocks this port without updating its configuration BPDU. The blocked port can receive BPDUs but cannot send BPDUs or forward data.

When the network topology is stable, only the root port and designated ports forward user traffic. Other ports are all in blocked state to receive BPDUs but not to forward BPDUs or user traffic.

Table 55 Selecting the optimum configuration BPDU

Step	Actions
1	<p>Upon receiving a configuration BPDU on a port, the device compares the priority of the received configuration BPDU with that of the configuration BPDU generated by the port. It takes one of the following actions:</p> <ul style="list-style-type: none"> • If the former priority is lower, the device discards the received configuration BPDU and keeps the configuration BPDU the port generated. • If the former priority is higher, the device replaces the content of the configuration BPDU generated by the port with the content of the received configuration BPDU.
2	<p>The device compares the configuration BPDUs of all the ports and chooses the optimum configuration BPDU.</p>

The following are the principles of configuration BPDU comparison:

- a. The configuration BPDU with the lowest root bridge ID has the highest priority.
- b. If all the configuration BPDUs have the same root bridge ID, their root path costs are compared. For example, the root path cost in a configuration BPDU plus the path cost of a receiving port is S. The configuration BPDU with the smallest S value has the highest priority.
- c. If all configuration BPDUs have the same root bridge ID and S value, their designated bridge IDs, designated port IDs, and the IDs of the receiving ports are compared in sequence. The configuration BPDU that contains a smaller designated bridge ID, designated port ID, or receiving port ID is selected.

A tree-shape topology forms when the root bridge, root ports, and designated ports are selected.

The following is an example of how the STP algorithm works. [Figure 179](#) provides an example showing how the STP algorithm works.

Figure 179 STP network

As shown in [Figure 179](#), the priority values of Device A, Device B, and Device C are 0, 1, and 2, and the path costs of links among the three devices are 5, 10 and 4, respectively.

The spanning tree calculation process is as follows:

4. Device state initialization.

In [Table 56](#), each configuration BPDU contains the following fields: root bridge ID, root path cost, designated bridge ID, and designated port ID.

Table 56 Initial state of each device

Device	Port name	BPDU of port
Device A	AP1	{0, 0, 0, AP1}
	AP2	{0, 0, 0, AP2}
Device B	BP1	{1, 0, 1, BP1}
	BP2	{1, 0, 1, BP2}
Device C	CP1	{2, 0, 2, CP1}
	CP2	{2, 0, 2, CP2}

5. Configuration BPDUs comparison on each device.

In [Table 57](#), each configuration BPDU contains the following fields: root bridge ID, root path cost, designated bridge ID, and designated port ID.

Table 57 Comparison process and result on each device

Device	Comparison process	Configuration BPDU on ports after comparison
Device A	<ul style="list-style-type: none"> Port AP1 receives the configuration BPDU of Device B {1, 0, 1, BP1}. Device A finds that the configuration BPDU of the local port {0, 0, 0, AP1} is superior to the received configuration BPDU, and it discards the received configuration BPDU. Port AP2 receives the configuration BPDU of Device C {2, 0, 2, CP1}. Device A finds that the BPDU of the local port {0, 0, 0, AP2} is superior to the received configuration BPDU, and it discards the received configuration BPDU. Device A finds that both the root bridge and designated bridge in the configuration BPDUs of all its ports are itself, so it assumes itself to be the root bridge. It does not make any change to the configuration BPDU of each port, and it starts sending out configuration BPDUs periodically. 	<ul style="list-style-type: none"> AP1: {0, 0, 0, AP1} AP2: {0, 0, 0, AP2}
Device B	<ul style="list-style-type: none"> Port BP1 receives the configuration BPDU of Device A {0, 0, 0, AP1}. Device B finds that the received configuration BPDU is superior to the configuration BPDU of the local port {1, 0, 1, BP1}, and it updates the configuration BPDU of BP1. Port BP2 receives the configuration BPDU of Device C {2, 0, 2, CP2}. Device B finds that the configuration BPDU of the local port {1, 0, 1, BP2} is superior to the received configuration BPDU, and it discards the received configuration BPDU. Device B compares the configuration BPDUs of all its ports, and determines that the configuration BPDU of BP1 is the optimum configuration BPDU. Then, it uses BP1 as the root port, the configuration BPDUs of which will not be changed. Based on the configuration BPDU of BP1 and the path cost of the root port (5), Device B calculates a designated port configuration BPDU for BP2 {0, 5, 1, BP2}. Device B compares the calculated configuration BPDU {0, 5, 1, BP2} with the configuration BPDU of BP2. If the calculated BPDU is superior, BP2 will act as the designated port, and the configuration BPDU on this port will be replaced with the calculated configuration BPDU, which will be sent out periodically. 	<ul style="list-style-type: none"> BP1: {0, 0, 0, AP1} BP2: {1, 0, 1, BP2} Root port BP1: {0, 0, 0, AP1} Designated port BP2: {0, 5, 1, BP2}
Device C	<ul style="list-style-type: none"> Port CP1 receives the configuration BPDU of Device A {0, 0, 0, AP2}. Device C finds that the received configuration BPDU is superior to the configuration BPDU of the local port {2, 0, 2, CP1}, and it updates the configuration BPDU of CP1. Port CP2 receives the configuration BPDU of port BP2 of Device B {1, 0, 1, BP2} before the configuration BPDU is updated. Device C finds that the received configuration BPDU is superior to the configuration BPDU of the local port {2, 0, 2, CP2}, and it updates the configuration BPDU of CP2. 	<ul style="list-style-type: none"> CP1: {0, 0, 0, AP2} CP2: {1, 0, 1, BP2}

Device	Comparison process	Configuration BPDU on ports after comparison
	<p>After comparison:</p> <ul style="list-style-type: none"> The configuration BPDU of CP1 is elected as the optimum configuration BPDU, so CP1 is identified as the root port, the configuration BPDUs of which will not be changed. Device C compares the calculated designated port configuration BPDU {0, 10, 2, CP2} with the configuration BPDU of CP2, and CP2 becomes the designated port, and the configuration BPDU of this port will be replaced with the calculated configuration BPDU. 	<ul style="list-style-type: none"> Root port CP1: {0, 0, 0, AP2} Designated port CP2: {0, 10, 2, CP2}
	<ul style="list-style-type: none"> Then, port CP2 receives the updated configuration BPDU of Device B {0, 5, 1, BP2}. Because the received configuration BPDU is superior to its own configuration BPDU, Device C launches a BPDU update process. At the same time, port CP1 receives periodic configuration BPDUs from Device A. Device C does not launch an update process after comparison. 	<ul style="list-style-type: none"> CP1: {0, 0, 0, AP2} CP2: {0, 5, 1, BP2}
	<p>After comparison:</p> <ul style="list-style-type: none"> Because the root path cost of CP2 (9) (root path cost of the BPDU (5) plus path cost corresponding to CP2 (4)) is smaller than the root path cost of CP1 (10) (root path cost of the BPDU (0) + path cost corresponding to CP2 (10)), the BPDU of CP2 is elected as the optimum BPDU, and CP2 is elected as the root port, the messages of which will not be changed. After comparison between the configuration BPDU of CP1 and the calculated designated port configuration BPDU, port CP1 is blocked, with the configuration BPDU of the port unchanged, and the port will not receive data from Device A until a spanning tree calculation process is triggered by a new event, for example, the link from Device B to Device C going down. 	<ul style="list-style-type: none"> Blocked port CP2: {0, 0, 0, AP2} Root port CP2: {0, 5, 1, BP2}

After the comparison processes described in [Table 57](#), a spanning tree with Device A as the root bridge is established, and the topology is as shown in [Figure 180](#).

Figure 180 The final calculated spanning tree

STP configuration BPDU forwarding mechanism

The configuration BPDUs of STP are forwarded according to these guidelines:

- Upon network initiation, every device regards itself as the root bridge, generates configuration BPDUs with itself as the root, and sends the configuration BPDUs at a regular hello interval.
- If the root port received a configuration BPDU and the received configuration BPDU is superior to the configuration BPDU of the port, the device increases the message age carried in the configuration BPDU following a certain rule and starts a timer to time the configuration BPDU while sending out this configuration BPDU through the designated port.
- If the configuration BPDU received on a designated port has a lower priority than the configuration BPDU of the local port, the port immediately sends its own configuration BPDU in response.
- If a path becomes faulty, the root port on this path no longer receives new configuration BPDUs and the old configuration BPDUs will be discarded because of timeout. The device generates configuration BPDUs with itself as the root and sends the BPDUs and TCN BPDUs. This triggers a new spanning tree calculation process to establish a new path to restore the network connectivity.

However, the newly calculated configuration BPDU cannot be propagated throughout the network immediately, so the old root ports and designated ports that have not detected the topology change continue forwarding data along the old path. If the new root ports and designated ports begin to forward data as soon as they are elected, a temporary loop might occur.

STP timers

STP calculation involves the following timers:

- **Forward delay**—The delay time for device state transition. A path failure can cause spanning tree recalculation to adapt the spanning tree structure to the change. However, the resulting new configuration BPDU cannot propagate throughout the network immediately. If the newly elected root ports and designated ports start to forward data immediately, a temporary loop is likely to occur.

For this reason, as a mechanism for state transition in STP, the newly elected root ports or designated ports require twice the forward delay time before they transit to the forwarding state, which makes sure the new configuration BPDU has propagated throughout the network.
- **Hello time**—The time interval at which a device sends hello packets to the neighboring devices to make sure that the paths are fault-free.
- **Max age**—A parameter used to determine whether a configuration BPDU held by the device has expired. The device discards the BPDU if the max age is exceeded.

RSTP

Developed based on the 802.1w standard of IEEE, RSTP is an optimized version of STP. It achieves rapid network convergence by allowing a newly elected root port or designated port to enter the forwarding state much faster than STP.

If the old root port on the device has stopped forwarding data and the upstream designated port has started forwarding data, a newly elected RSTP root port rapidly enters the forwarding state.

A newly elected RSTP designated port rapidly enters the forwarding state if it is an edge port (a port that directly connects to a user terminal rather than to another network device or a shared LAN segment) or it connects to a point-to-point link. Edge ports directly enter the forwarding state. Connecting to a point-to-point link, a designated port enters the forwarding state immediately after the device receives a handshake response from the directly connected device.

MSTP

MSTP overcomes the following STP and RSTP limitations:

- **STP limitations**—STP does not support rapid state transition of ports. A newly elected port must wait twice the forward delay time before it transits to the forwarding state, even if it connects to a point-to-point link or is an edge port.
- **RSTP limitations**—Although RSTP enables faster network convergence than STP, RSTP fails to provide load balancing among VLANs. As with STP, all RSTP bridges in a LAN share one spanning tree and forward packets from all VLANs along this spanning tree.

MSTP features

Developed based on IEEE 802.1s, MSTP overcomes the limitations of STP and RSTP. In addition to supporting rapid network convergence, it provides a better load sharing mechanism for redundant links by allowing data flows of different VLANs to be forwarded along separate paths.

MSTP provides the following features:

- MSTP supports mapping VLANs to MST instances (MSTIs) by means of a VLAN-to-instance mapping table. MSTP can reduce communication overheads and resource usage by mapping multiple VLANs to one MSTI.
- MSTP divides a switched network into multiple regions, each containing multiple spanning trees that are independent of one another.
- MSTP prunes a loop network into a loop-free tree, which avoids proliferation and endless cycling of packets in a loop network. In addition, it supports load balancing of VLAN data by providing multiple redundant paths for data forwarding.
- MSTP is compatible with STP and RSTP.

MSTP basic concepts

Figure 181 shows a switched network that comprises four MST regions, each MST region comprising four MSTP devices. Figure 182 shows the networking topology of MST region 3.

Figure 181 Basic concepts in MSTP

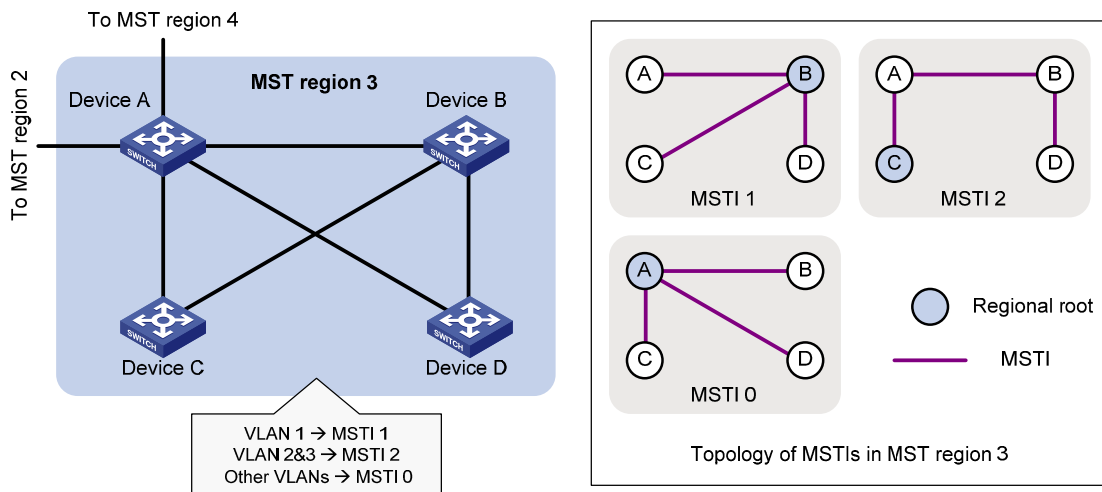

Figure 182 Network diagram and topology of MST region 3

MST region

A multiple spanning tree region (MST region) consists of multiple devices in a switched network and the network segments among them. All these devices have the following characteristics:

- A spanning tree protocol enabled.
- Same region name.

- Same VLAN-to-instance mapping configuration.
- Same MSTP revision level.
- Physically linked together.

Multiple MST regions can exist in a switched network. You can assign multiple devices to the same MST region. In [Figure 181](#), the switched network comprises four MST regions, MST region 1 through MST region 4, and all devices in each MST region have the same MST region configuration.

MSTI

MSTP can generate multiple independent spanning trees in an MST region, and each spanning tree is mapped to a range of VLANs. Each spanning tree is referred to as a "multiple spanning tree instance (MSTI)".

In [Figure 182](#), MST region 3 comprises three MSTIs, MSTI 1, MSTI 2, and MSTI 0.

VLAN-to-instance mapping table

As an attribute of an MST region, the VLAN-to-instance mapping table describes the mapping relationships between VLANs and MSTIs.

In [Figure 182](#), the VLAN-to-instance mapping table of MST region 3 is: VLAN 1 to MSTI 1, VLAN 2 and VLAN 3 to MSTI 2, and other VLANs to MSTI 0. MSTP achieves load balancing by means of the VLAN-to-instance mapping table.

CST

The common spanning tree (CST) is a single spanning tree that connects all MST regions in a switched network. If you regard each MST region as a device, the CST is a spanning tree calculated by these devices through STP or RSTP.

The blue lines in [Figure 181](#) represent the CST.

IST

An internal spanning tree (IST) is a spanning tree that runs in an MST region. It is also called MSTI 0, a special MSTI to which all VLANs are mapped by default.

In [Figure 181](#), MSTI 0 is the IST in MST region 3.

CIST

The common and internal spanning tree (CIST) is a single spanning tree that connects all devices in a switched network. It consists of the ISTs in all MST regions and the CST.

In [Figure 181](#), the ISTs (MSTI 0) in all MST regions plus the inter-region CST constitute the CIST of the entire network.

Regional root

The root bridge of the IST or an MSTI within an MST region is the regional root of the IST or MSTI. Based on the topology, different spanning trees in an MST region might have different regional roots.

In MST region 3 in [Figure 182](#), the regional root of MSTI 1 is Device B, the regional root of MSTI 2 is Device C, and the regional root of MSTI 0 (also known as the IST) is Device A.

Common root bridge

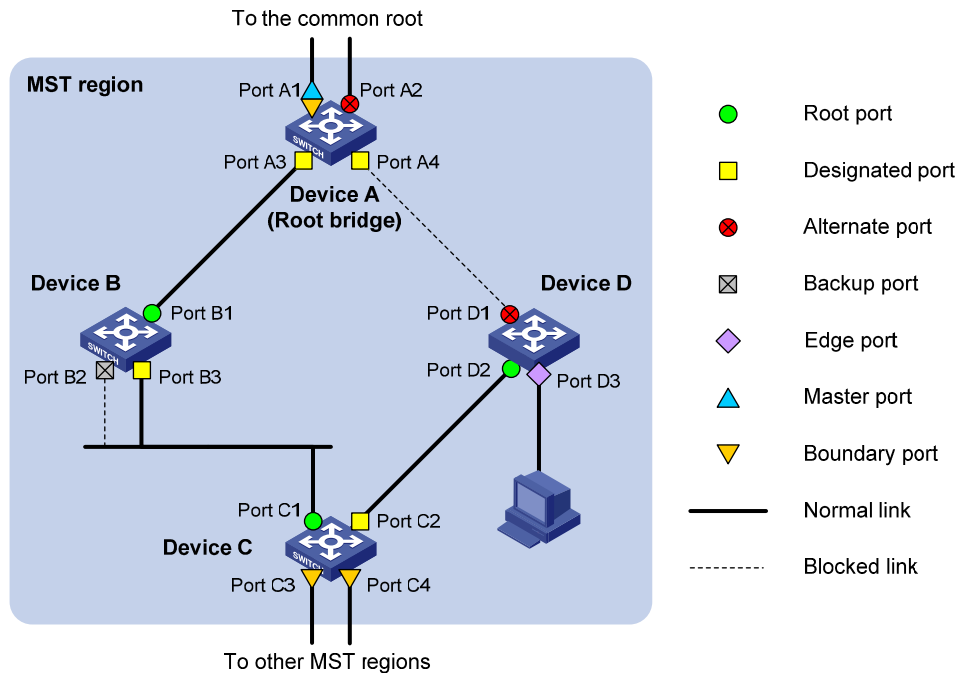

The common root bridge is the root bridge of the CIST.

In [Figure 181](#), the common root bridge is a device in MST region 1.

Port roles

A port can play different roles in different MSTIs. As shown in Figure 183, an MST region has Device A, Device B, Device C, and Device D. Port A1 and port A2 of Device A connect to the common root bridge. Port B2 and Port B3 of Device B form a loop. Port C3 and Port C4 of Device C connect to other MST regions. Port D3 of Device D directly connects to a host.

Figure 183 Port roles

MSTP calculation involves the following port roles:

- **Root port**—Forwards data for a non-root bridge to the root bridge. The root bridge does not have any root port.
- **Designated port**—Forwards data to the downstream network segment or device.
- **Alternate port**—The backup port for a root port or master port. When the root port or master port is blocked, the alternate port takes over.
- **Backup port**—The backup port of a designated port. When the designated port is invalid, the backup port becomes the new designated port. A loop occurs when two ports of the same spanning tree device are interconnected, so the device blocks one of the ports. The blocked port acts as the backup.
- **Edge port**—An edge port does not connect to any network device or network segment, but directly connects to a user host.
- **Master port**—A port on the shortest path from the local MST region to the common root bridge. The master port is not always located on the regional root. It is a root port on the IST or CIST and still a master port on the other MSTIs.
- **Boundary port**—Connects an MST region to another MST region or to an STP/RSTP-running device. In MSTP calculation, a boundary port's role on an MSTI is consistent with its role on the CIST. But that is not true with master ports. A master port on MSTIs is a root port on the CIST.

Port states

In MSTP, a port can be in one of the following states:

- **Forwarding**—The port receives and sends BPDUs, learns MAC addresses, and forwards user traffic.
- **Learning**—The port receives and sends BPDUs, learns MAC addresses, but does not forward user traffic. Learning is an intermediate port state.
- **Discarding**—The port receives and sends BPDUs, but does not learn MAC addresses or forward user traffic.

NOTE:

When in different MSTIs, a port can be in different states.

A port state is not exclusively associated with a port role. [Table 58](#) lists the port states that each port role supports. (A check mark [✓] indicates that the port supports this state, while a dash [—] indicates that the port does not support this state.)

Table 58 Port states that different port roles support

Port role (right) Port state (below)	Root port/master port	Designated port	Alternate port	Backup port
Forwarding	✓	✓	—	—
Learning	✓	✓	—	—
Discarding	✓	✓	✓	✓

How MSTP works

MSTP divides an entire Layer 2 network into multiple MST regions, which are connected by a calculated CST. Inside an MST region, multiple spanning trees, called MSTIs, are calculated. Among these MSTIs, MSTI 0 is the CIST.

Similar to RSTP, MSTP uses configuration BPDUs to calculate spanning trees. An important difference is that an MSTP BPDU carries the MSTP configuration of the bridge from which the BPDU is sent.

CIST calculation

The calculation of a CIST tree is also the process of configuration BPDU comparison. During this process, the device with the highest priority is elected as the root bridge of the CIST. MSTP generates an IST within each MST region through calculation. At the same time, MSTP regards each MST region as a single device and generates a CST among these MST regions through calculation. The CST and ISTs constitute the CIST of the entire network.

MSTI calculation

Within an MST region, MSTP generates different MSTIs for different VLANs based on the VLAN-to-instance mappings. For each spanning tree, MSTP performs a separate calculation process, which is similar to spanning tree calculation in STP/RSTP. For more information, see "[How STP works](#)."

In MSTP, a VLAN packet is forwarded along the following paths:

- Within an MST region, the packet is forwarded along the corresponding MSTI.
- Between two MST regions, the packet is forwarded along the CST.

MSTP implementation on devices

MSTP is compatible with STP and RSTP. STP and RSTP protocol packets can be recognized by devices running MSTP and used for spanning tree calculation.

In addition to basic MSTP functions, the device provides the following functions for ease of management:

- Root bridge hold
- Root bridge backup
- Root guard
- BPDU guard
- Loop guard
- TC-BPDU (a message that notifies the device of topology changes) guard

Protocols and standards

MSTP is documented in the following protocols and standards:

- IEEE 802.1d, *Spanning Tree Protocol*
- IEEE 802.1w, *Rapid Spanning Tree Protocol*
- IEEE 802.1s, *Multiple Spanning Tree Protocol*

Configuration restrictions and guidelines

When you configure MSTP, follow these restrictions and guidelines:

- Two or more spanning tree devices belong to the same MST region only if they are configured to have the same MST region name, MST region level, and the same VLAN-to-instance mapping entries in the MST region, and they are connected through a physical link.
- If two or more devices are selected as the root bridge in a spanning tree at the same time, the device with the lowest MAC address is chosen.
- If BPDU guard is disabled, a port set as an edge port becomes a non-edge port again if it receives a BPDU from another port. To restore its port role as an edge port, you must restart the port.
- If a port directly connects to a user terminal, configure it as an edge port and enable BPDU guard for it. This enables the port to quickly transit to the forwarding state and ensures network security.

Recommended MSTP configuration procedure

Step	Remarks
1. Configuring an MST region	<p>Optional.</p> <p>Configure the MST region-related parameters and VLAN-to-instance mappings.</p> <p>By default, the MST region-related parameters adopt the default values, and all VLANs in an MST region are mapped to MSTI 0.</p>

Step	Remarks
2. Configuring MSTP globally	Required. Enable STP globally and configure MSTP parameters. By default, STP is disabled globally. All MSTP parameters have default values.
3. Configuring MSTP on a port	Optional. Enable MSTP on a port and configure MSTP parameters. By default, MSTP is enabled on a port, and all MSTP parameters adopt the default values.
4. Displaying MSTP information of a port	Optional. Display MSTP information of a port in MSTI 0, the MSTI to which the port belongs, and the path cost and priority of the port.

Configuring an MST region

- From the navigation tree, select **Network** > **MSTP**.
By default, the **Region** tab is displayed.

Figure 184 MST region

Region	Global	Port Summary	Port Setup
--------	--------	--------------	------------

Format Selector	Region Name	Revision Level
0	00e0fc003620	0

[Modify](#)

Instance	VLAN Mapped
0	1 to 4094

- Click **Modify**.

Figure 185 Configuring an MST region

Region	Global	Port Summary	Port Setup
Region Name	<input type="text" value="00e0fc003620"/> (1-32 Chars.)		
Revision Level	<input type="text" value="0"/> (0-65535, Default = 0)		
<input checked="" type="radio"/> Manual <input type="radio"/> Modulo			
Instance ID	<input type="text" value="1"/>	VLAN ID	<input type="text"/> (Example:1,3,5-10)
			<input type="button" value="Apply"/> <input type="button" value="Remove"/>
Instance ID	VLAN Mapped		
<div></div>			
			<input type="button" value="Activate"/> <input type="button" value="Cancel"/>

3. Configure the MST region information as described in [Table 59](#), and click **Apply**.

Table 59 Configuration items

Item	Description
Region Name	MST region name. By default, the MST region name is the bridge MAC address of the device.
Revision Level	Revision level of the MST region.
Manual (Instance ID and VLAN ID)	Manually add VLAN-to-instance mappings. Click Apply to add the VLAN-to-instance mapping entries to the list.
Modulo	The device automatically maps 4094 VLANs to the corresponding MSTIs based on the modulo value.

4. Click **Activate**.

Configuring MSTP globally

1. From the navigation tree, select **Network > MSTP**.
2. Click the **Global** tab.

Figure 186 Configuring MSTP globally

Region	Global	Port Summary	Port Setup

- Configure the global MSTP configuration as described in [Table 60](#), and then click **Apply**.

Table 60 Configuration items

Item	Description
Enable STP Globally	Select whether to enable STP globally. Other MSTP configurations take effect only after you enable STP globally.
BPDU Guard	Select whether to enable BPDU guard. BPDU guard can protect the device from malicious BPDU attacks, making the network topology stable.

Item	Description
Mode	<p>Set the operating mode of STP:</p> <ul style="list-style-type: none"> • STP—Each port on a device sends out STP BPDUs. • RSTP—Each port on a device sends out RSTP BPDUs, and automatically migrates to STP-compatible mode when detecting that it is connected with a device running STP. • MSTP—Each port on a device sends out MSTP BPDUs, and automatically migrates to STP-compatible mode when detecting that it is connected with a device running STP.
Max Hops	<p>Set the maximum number of hops in an MST region to restrict the region size. The setting can take effect only when it is configured on the regional root bridge.</p>
Path Cost Standard	<p>Specify the standard for path cost calculation. It can be Legacy, IEEE 802.1D-1998, or IEEE 802.1T.</p>
Bridge Diameter	<p>Any two stations in a switched network are interconnected through a specific path composed of a series of devices. The bridge diameter (or the network diameter) is the number of devices on the path composed of the most devices.</p> <p>After you set the network diameter, you cannot set the timers. Instead, the device automatically calculates the forward delay, hello time, and max age.</p> <p>! IMPORTANT:</p> <ul style="list-style-type: none"> • The configured network diameter takes effect only on the CIST, not on other MSTIs. • The bridge diameter cannot be configured together with the timers.
Timers	<p>Configure the timers:</p> <ul style="list-style-type: none"> • Forward Delay—Set the delay for the root and designated ports to transit to the forwarding state. • Hello Time—Set the interval at which the device sends hello packets to the surrounding devices to make sure the paths are fault-free. • Max Age—Set the maximum length of time a configuration BPDU can be held by the device. <p>! IMPORTANT:</p> <ul style="list-style-type: none"> • The settings of hello time, forward delay and max age must meet a certain formula. Otherwise, the network topology will not be stable. HP recommends you to set the network diameter, and then have the device automatically calculate the forward delay, hello time, and max age. • The bridge diameter cannot be configured together with the timers.
Instance (Instance ID, Root Type, and Bridge Priority)	<p>Set the role of the device in the MSTI or the bridge priority of the device, which is one of the factors deciding whether the device can be elected as the root bridge.</p> <p>Role of the device in the MSTI:</p> <ul style="list-style-type: none"> • Not Set—Not set (you can set the bridge priority of the device when selecting this role) • Primary—Configure the device as the root bridge (you cannot set the bridge priority of the device when selecting this role) • Secondary—Configure the device as a secondary root bridge (you cannot set the bridge priority of the device when selecting this role).

Item	Description
tc-protection	<p>Select whether to enable TC-BPDU guard.</p> <p>When receiving topology change (TC) BPDUs, the device flushes its forwarding address entries. If someone forges TC-BPDUs to attack the device, the device will receive a large number of TC-BPDUs within a short time and frequently flushes its forwarding address entries. This affects network stability.</p> <p>With the TC-BPDU guard function, you can prevent frequent flushing of forwarding address entries.</p> <p>NOTE:</p> <p>HP recommends not disabling this function.</p>
tc-protection threshold	Set the maximum number of immediate forwarding address entry flushes the device can perform within a certain period of time after receiving the first TC-BPDU.

Configuring MSTP on a port

1. From the navigation tree, select **Network > MSTP**.
2. Click the **Port Setup** tab.

Figure 187 MSTP configuration on a port

The screenshot shows the 'Port Setup' tab in a network configuration interface. At the top, there are tabs for 'Region', 'Global', 'Port Summary', and 'Port Setup'. Below the tabs, there are two dropdown menus: 'STP:' and 'Protection:', both set to 'No Change'. A note states: 'Note : The new protection will replace the old one'. Below these are expandable sections for '+Instance' and '+Advanced'. The 'Select port(s):' section displays a port selection interface with a grid of ports (1-8) and a separate port 9. The grid is labeled 'HP 1910-8G-PoE+'. Below the grid are 'Select All' and 'Select None' buttons. The 'Selected port(s):' section is an empty list box. At the bottom, there are 'Apply' and 'Cancel' buttons.

3. Configure MSTP for ports as described in [Table 61](#), and then click **Apply**.

Table 61 Configuration items

Item	Description
STP	Select whether to enable STP on the port.

Item	Description
Protection	<p>Set the type of protection to be enabled on the port:</p> <ul style="list-style-type: none"> • Not Set—No protection is enabled on the port. • Edged Port, Root Protection, Loop Protection—For more information, see Table 62.
Instance (Instance ID, Port Priority, Auto Path Cost, and Manual Path Cost)	<p>Set the priority and path cost of the port in the current MSTI.</p> <ul style="list-style-type: none"> • The priority of a port is an important factor in determining whether the port can be elected as the root port of a device. If all other conditions are the same, the port with the highest priority will be elected as the root port. On an MSTP-enabled device, a port can have different priorities in different MSTIs, and the same port can play different roles in different MSTIs, so that data of different VLANs can be propagated along different physical paths, implementing per-VLAN load balancing. You can set port priority values based on the actual networking requirements. • Path cost is a parameter related to the rate of a port. On an MSTP-enabled device, a port can have different path costs in different MSTIs. Setting appropriate path costs allows VLAN traffic flows to be forwarded along different physical links, achieving VLAN-based load balancing. The device can automatically calculate the default path cost; alternatively, you can also manually configure path cost for ports.
Advanced	<ul style="list-style-type: none"> • Point to Point Specify whether the port is connected to a point-to-point link: <ul style="list-style-type: none"> ◦ Auto—Configure the device to automatically detect whether or not the link type of the port is point-to-point. ◦ Force False—The link type for the port is not point-to-point link. ◦ Force True—The link type for the port is point-to-point link. <p>! IMPORTANT:</p> <p>If a port is configured as connecting to a point-to-point link, the setting takes effect on the port in all MSTIs. If the physical link to which the port connects is not a point-to-point link and you force it to be a point-to-point link by configuration, the configuration might incur a temporary loop.</p> <ul style="list-style-type: none"> • Transmit Limit Configure the maximum number of MSTP packets that can be sent during each Hello interval. The larger the transmit limit is, the more network resources will be occupied. HP recommends that you use the default value. • MSTP Mode Set whether the port migrates to the MSTP mode. In a switched network, if a port on an MSTP (or RSTP) device connects to a device running STP, this port will automatically migrate to the STP-compatible mode. After the device running STP is removed, the port on the MSTP (or RSTP) device might not be able to migrate automatically to the MSTP (or RSTP) mode, but will remain operating in the STP-compatible mode. You can set this option to enable the port to automatically migrate to the MSTP (or RSTP) mode.
Select port(s)	<p>Select one or multiple ports on which you want to configure MSTP on the chassis front panel. If aggregate interfaces are configured on the device, the page displays a list of aggregate interfaces below the chassis front panel. You can select aggregate interfaces from this list.</p>

Table 62 Protection types

Protection type	Description
Edged Port	<p>Set the port as an edge port.</p> <p>Some ports of access layer devices are directly connected to PCs or file servers, which cannot generate BPDUs. You can set these ports as edge ports to achieve fast transition for these ports.</p> <p>HP recommends that you enable the BPDU guard function in conjunction with the edged port function to avoid network topology changes when the edge ports receive configuration BPDUs.</p>
Root Protection	<p>Enable the root guard function.</p> <p>Configuration errors or attacks might result in configuration BPDUs with their priorities higher than that of a root bridge, which causes a new root bridge to be elected and network topology change to occur. The root guard function is used to address such a problem.</p>
Loop Protection	<p>Enable the loop guard function.</p> <p>By keeping receiving BPDUs from the upstream device, a device can maintain the state of the root port and other blocked ports. These BPDUs might get lost because of network congestion or unidirectional link failures. The device will re-elect a root port, and blocked ports might transit to the forwarding state, causing loops in the network. The loop guard function is used to address such a problem.</p>

Displaying MSTP information of a port

1. From the navigation tree, select **Network > MSTP**.
2. Click the **Port Summary** tab.
3. Select a port (GigabitEthernet 1/0/16 for example) on the chassis front panel.

If aggregate interfaces are configured on the device, the page displays a list of aggregate interfaces below the chassis front panel. You can select aggregate interfaces from this list. The lower part of the page displays the MSTP information of the port in MSTI 0 (when STP is enabled globally) or the STP status and statistics (when STP is not enabled globally), the MSTI to which the port belongs, and the path cost and priority of the port in the MSTI.

Table 63 Field description

Field	Description
[FORWARDING]	The port is in forwarding state, so the port learns MAC addresses and forwards user traffic.
[LEARNING]	The port is in learning state, so the port learns MAC addresses but does not forward user traffic.
[DISCARDING]	The port is in discarding state, so the port does not learn MAC addresses or forward user traffic.
[DOWN]	The port is down.
Port Protocol	Whether STP is enabled on the port.
Port Role	Port role, which can be Alternate, Backup, Root, Designated, Master, or Disabled.
Port Priority	Port priority.
Port Cost(Legacy)	Path cost of the port. The field in the bracket indicates the standard used for port path cost calculation, which can be legacy , dot1d-1998 , or dot1t . Config indicates the configured value, and Active indicates the actual value.
Desg. Bridge/Port	Designated bridge ID and port ID of the port The port ID displayed is insignificant for a port that does not support port priority.
Port Edged	Whether the port is an edge port: <ul style="list-style-type: none"> • Config—The configured value. • Active—The actual value.

Field	Description
Point-to-point	Whether the port is connected to a point-to-point link: <ul style="list-style-type: none"> • Config—The configured value. • Active—The actual value.
Transmit Limit	Maximum number of packets sent within each Hello time.
Protection Type	Protection type on the port,: <ul style="list-style-type: none"> • Root—Root guard • Loop—Loop guard • BPDU—BPDU guard • None—No protection
MST BPDU Format	Format of the MST BPDUs that the port can send, which can be legacy or 802.1s. Config indicates the configured value, and Active indicates the actual value.
Port Config-Digest-Snooping	Whether digest snooping is enabled on the port.
Rapid transition	Whether the current port rapidly transitions to the forwarding state.
Num of Vlans Mapped	Number of VLANs mapped to the current MSTI.
PortTimes	Major parameters for the port: <ul style="list-style-type: none"> • Hello—Hello timer • MaxAge—Max Age timer • FwDly—Forward delay timer • MsgAge—Message Age timer • Remain Hop—Remaining hops
BPDU Sent	Statistics on sent BPDUs.
BPDU Received	Statistics on received BPDUs.
Protocol Status	Whether MSTP is enabled.
Protocol Std.	MSTP standard.
Version	MSTP version.
CIST Bridge-Prio.	Priority of the current device in the CIST.
MAC address	MAC address of the current device.
Max age(s)	Maximum age of a configuration BPDU.
Forward delay(s)	Port state transition delay, in seconds.
Hello time(s)	Configuration BPDU transmission interval, in seconds.
Max hops	Maximum hops of the current MST region.

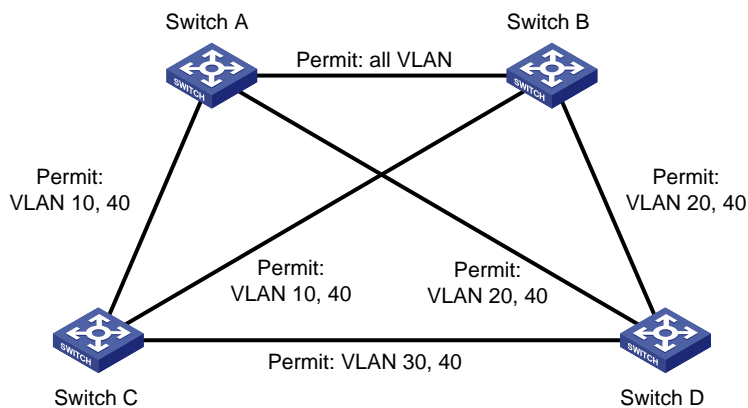

MSTP configuration example

Network requirements

As shown in [Figure 189](#), configure MSTP as follows:

- All devices on the network are in the same MST region.
- Packets of VLAN 10, VLAN 20, VLAN 30, and VLAN 40 are forwarded along MSTI 1, MSTI 2, MSTI 3, and MSTI 0, respectively.
- Switch A and Switch B operate at the distribution layer; Switch C and Switch D operate at the access layer. VLAN 10 and VLAN 20 are terminated on the distribution layer devices, and VLAN 30 is terminated on the access layer devices, so the root bridges of MSTI 1 and MSTI 2 are Switch A and Switch B, respectively, and the root bridge of MSTI 3 is Switch C.

Figure 189 Network diagram

NOTE:

"Permit:" next to a link in the figure is followed by the VLANs the packets of which are permitted to pass this link.

Configuration procedure

Configuring Switch A

1. Configure an MST region:
 - a. From the navigation tree, select **Network > MSTP**.
By default, the **Region** tab is displayed.
 - b. Click **Modify**.

Figure 190 The region tab

Region	Global	Port Summary	Port Setup						
<table border="1"> <thead> <tr> <th>Format Selector</th> <th>Region Name</th> <th>Revision Level</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>00e0fc003620</td> <td>0</td> </tr> </tbody> </table>				Format Selector	Region Name	Revision Level	0	00e0fc003620	0
Format Selector	Region Name	Revision Level							
0	00e0fc003620	0							
<div style="border: 1px solid red; padding: 2px; display: inline-block;">Modify</div>									
<table border="1"> <thead> <tr> <th>Instance</th> <th>VLAN Mapped</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>1 to 4094</td> </tr> </tbody> </table>				Instance	VLAN Mapped	0	1 to 4094		
Instance	VLAN Mapped								
0	1 to 4094								

- c. Set the region name to **example**.
- d. Set the revision level to **0**.

- e. Select **Manual**.
- f. Select **1** from the **Instance ID** list.
- g. Set the VLAN ID to **10**.
- h. Click **Apply**.
The system maps VLAN 10 to MSTI 1 and adds the VLAN-to-instance mapping entry to the VLAN-to-instance mapping list.
- i. Repeat the preceding three steps to map VLAN 20 to MSTI 2 and VLAN 30 to MSTI 3 and add the VLAN-to-instance mapping entries to the VLAN-to-instance mapping list.
- j. Click **Activate**.

Figure 191 Configuring an MST region

Region	Global	Port Summary	Port Setup
Region Name	example (1-32 Chars.)		
Revision Level	0 (0-65535, Default = 0)		
<input checked="" type="radio"/> Manual <input type="radio"/> Module

		Apply	Remove
Instance ID	VLAN Mapped		
1	10		
2	20		
3	30		
		Activate	Cancel

2. Configure MSTP globally:
 - a. From the navigation tree, select **Network > MSTP**.
 - b. Click the **Global** tab.
 - c. Select **Enable** from the **Enable STP Globally** list.
 - d. Select **MSTP** from the **Mode** list.
 - e. Select the box before **Instance**.
 - f. Set the **Instance ID** field to **1**.
 - g. Set the **Root Type** field to **Primary**.
 - h. Click **Apply**.

Figure 192 Configuring MSTP globally (on Switch A)

Region	Global	Port Summary	Port Setup
--------	--------	--------------	------------

Global MSTP Configuration

Enable STP Globally:	Enable
BPDU Protection:	Disable
Mode:	MSTP
Max Hops:	20
Path Cost Standard:	Legacy

<input type="checkbox"/> Bridge Diameter:	7
<input type="checkbox"/> Timer(in centiseconds)

Instance ID:	1
Root Type:	Primary
Bridge Priority:	32768
TC Protection:	Enable
TC Protection Threshold:	6 (1-255, default=6)

Apply

Configuring Switch B

1. Configure an MST region on the switch in the same way the MST region is configured on Switch A.
2. Configure MSTP globally:
 - a. From the navigation tree, select **Network > MSTP**.
 - b. Click the **Global** tab.
 - c. Select **Enable** from the **Enable STP Globally** list.
 - d. Select **MSTP** from the **Mode** list.
 - e. Select the box before **Instance**.
 - f. Set the **Instance ID** field to **2**.
 - g. Set the **Root Type** field to **Primary**.
 - h. Click **Apply**.

Configuring Switch C

1. Configure an MST region on the switch in the same way the MST region is configured on Switch A.
2. Configure MSTP globally:
 - a. From the navigation tree, select **Network > MSTP**.
 - b. Click **Global**.
 - c. Select **Enable** from the **Enable STP Globally** list.
 - d. Select **MSTP** from the **Mode** list.
 - e. Select the box before **Instance**.
 - f. Set the **Instance ID** field to **3**.
 - g. Set the **Root Type** field to **Primary**.
 - h. Click **Apply**.

Configuring Switch D

1. Configure an MST region on the switch in the same way the MST region is configured on Switch A.
2. Configure MSTP globally:
 - a. From the navigation tree, select **Network > MSTP**.
 - b. Click **Global**.
 - c. Select **Enable** from the **Enable STP Globally** list.
 - d. Select **MSTP** from the **Mode** list.
 - e. Click **Apply**.

Configuring link aggregation and LACP

Overview

Ethernet link aggregation bundles multiple physical Ethernet links into one logical link, called an aggregate link. Link aggregation has the following benefits:

- Increased bandwidth beyond the limits of any single link. In an aggregate link, traffic is distributed across the member ports.
- Improved link reliability. The member ports dynamically back up one another. When a member port fails, its traffic is automatically switched to other member ports.

Basic concepts

Aggregation group, member port, and aggregate interface

Link aggregation is implemented through link aggregation groups. An aggregation group is a group of Ethernet interfaces bundled together, which are called member ports of the aggregation group. For each aggregation group, a logical interface (called an aggregate interface) is created.

Aggregation states of the member ports in an aggregation group

A member port in an aggregation group can be in either of the following states:

- **Selected**—A Selected port can forward user traffic.
- **Unselected**—An Unselected port cannot forward user traffic.

The port rate of an aggregate interface equals the total rate of its member ports in Selected state, and its duplex mode is the same as that of the selected member ports.

For more information about the states of member ports in an aggregation group, see "[Static aggregation mode](#)" and "[Dynamic aggregation mode](#)."

LACP

The Link Aggregation Control Protocol (LACP) is defined in IEEE 802.3ad. It uses link aggregation control protocol data units (LACPDU) to exchange information between LACP-enabled devices.

LACP is automatically enabled on member ports in a dynamic aggregation group. For information about dynamic aggregation groups, see "[Dynamic aggregation mode](#)." An LACP-enabled port sends LACPDUs to notify the remote system (the partner) of its system LACP priority, system MAC address, LACP port priority, port number, and operational key. Upon receiving an LACPDU, the peer port compares the received information with the information received on other member ports. In this way, the two systems reach an agreement on which link aggregation member ports are placed in Selected state.

Operational key

When aggregating ports, link aggregation control automatically assigns each port an operational key based on port attributes, including the port rate, duplex mode, and link state configuration.

In an aggregation group, all Selected ports are assigned the same operational key.

Configuration classes

Port configurations include the following classes:

- **Class-two configurations**—A member port can be placed in Selected state only if it has the same class-two configurations as the aggregate interface.

Table 64 Class-two configurations

Type	Considerations
Port isolation	Whether a port has joined an isolation group, and the isolation group that the port belongs to
VLAN	Permitted VLAN IDs, port VLAN ID (PVID), link type (trunk, hybrid, or access), IP subnet-based VLAN configuration, protocol-based VLAN configuration, and VLAN tagging mode
MAC address learning	MAC address learning capability, MAC address learning limit, forwarding of frames with unknown destination MAC addresses after the upper limit of the MAC address table is reached

Any class-two configuration change might affect the aggregation state of link aggregation member ports and running services. To make sure that you are aware of the risk, the system displays a warning message every time you attempt to change a class-two configuration setting on a member port.

- **Class-one configurations**—Include settings that do not affect the aggregation state of the member port even if they are different from those on the aggregate interface. For example, MSTP, can be configured on aggregate interfaces and member ports. However, class-one configurations do not take effect in operational key calculation.

Link aggregation modes

Based on the link aggregation procedure, link aggregation operates in one of the following modes:

- [Static aggregation mode](#)
- [Dynamic aggregation mode](#)

Static aggregation mode

LACP is disabled on the member ports in a static aggregation group. In a static aggregation group, the system sets the aggregation state of each member port according to the following rules:

1. Choose a reference port from the member ports that are in up state and with the same class-two configurations as the aggregate interface. The candidate ports are sorted in the following order:
 - Full duplex/high speed
 - Full duplex/low speed
 - Half duplex/high speed
 - Half duplex/low speedIf two ports have the same duplex mode/speed pair, the one with the lower port number is chosen.
2. Place the ports in up state with the same port attributes and class-two configurations as the reference port in Selected state, and place all others in Unselected state.
3. The number of Selected ports is limited in a static aggregation group. When the number of the Selected ports is under the limit, all the member ports become Selected ports. When the limit is

exceeded, place the candidate selected ports with smaller port numbers in the Selected state and those with greater port numbers in the Unselected state.

4. Place the member ports in the Unselected state if all the member ports are down.
5. Place the ports that cannot aggregate with the reference port in the Unselected state, for example, as a result of the inter-board aggregation restriction.

After a static aggregation group has reached the limit on Selected ports, any port that joins the group is placed in Unselected state to avoid traffic interruption on the existing Selected ports. However, the state of link aggregation member ports might change after a reboot.

Dynamic aggregation mode

LACP is enabled on member ports in a dynamic aggregation group.

In a dynamic aggregation group, a Selected port can receive and send LACPDU. An Unselected port can receive and send LACPDU only when it is up and has the same configurations as the aggregate interface.

In a dynamic aggregation group, the local system (the actor) negotiates with the remote system (the partner) to determine the aggregation state of each port in the following steps:

1. Compare the system IDs (A system ID comprises the system LACP priority and the system MAC address). The lower the LACP priority, the smaller the system ID. If LACP priority values are the same, the two systems compare their system MAC addresses. The lower the MAC address, the smaller the system ID.
2. The system with the smaller system ID chooses the port with the smallest port ID as the reference port. (A port ID comprises a port priority and a port number.) The port with the lower priority value is chosen. If two ports have the same aggregation priority, the system compares their port numbers. The port with the smaller port number becomes the reference port.
3. If a port in up state is with the same port attributes and class-two configuration as the reference port, and the peer port of the port is with the same port attributes and class-two configurations as the peer port of the reference port, consider the port as a candidate selected port; otherwise place the port in the Unselected state.

The number of Selected ports in an aggregation group is limited. When the number of Selected ports is under the limit, all the member ports are set to Selected state. When the limit is exceeded, the system sets the candidate selected ports with smaller port IDs as the Selected ports, and place other ports in the Unselected state. At the same time, the peer device, being aware of the changes, sets the aggregation state of local member ports the same as their peer ports.

The system places the ports that cannot aggregate with the reference port in the Unselected state, for example, as the result of the inter-board aggregation restriction.

When you configure static and dynamic aggregation modes, follow these guidelines:

- In an aggregation group, a Selected port must have the same port attributes and class-two configurations as the reference port. To keep these configurations consistent, you should configure the port manually.
- Any port attribute or class-two configuration change might affect the aggregation state of all member ports and ongoing traffic. If you need to make this change, make sure you understand its impact on the live network.

Configuration procedures

Configuring a static aggregation group

Step	Remarks
1. Creating a link aggregation group	Create a static aggregate interface and configure member ports for the static aggregation group. By default, no link aggregation group exists.
2. (Optional.) Displaying aggregate interface	Display detailed information of an existing aggregation group.

Configuring a dynamic aggregation group

Step	Remarks
1. Creating a link aggregation group	Create a dynamic aggregate interface and configure member ports for the dynamic aggregation group automatically created. LACP is enabled automatically on all the member ports. By default, no link aggregation group exists.
2. (Optional.) Displaying aggregate interface	Display detailed information of an existing aggregation group.
3. (Optional.) Setting LACP priority	Set LACP priority for the local system and link aggregation member ports. Changes of LACP priorities affect the aggregation state of the member ports. The default port LACP priority and system LACP priority are both 32768.
4. (Optional.) Displaying LACP-enabled port	Display detailed information of LACP-enabled ports and the corresponding remote (partner) ports.

Creating a link aggregation group

1. From the navigation tree, select **Network > Link Aggregation**.
2. Click **Create** to enter the page as shown in [Figure 194](#).

Link aggregation and LACP configuration example

Network requirements

As shown in [Figure 198](#), aggregate the ports on each device to form a link aggregation group, distributing incoming and outgoing traffic across the member ports.

Figure 198 Network diagram

You can create a static or dynamic link aggregation group to achieve load sharing.

Method 1: Create static link aggregation group 1

1. From the navigation tree, select **Network > Link Aggregation**.
2. Click **Create** to enter the page as shown in [Figure 199](#).
3. Configure static link aggregation group 1:

- a. Enter link aggregation interface ID **1**.
- b. Select the **Static (LACP Disabled)** option for the aggregate interface type.
- c. Select GigabitEthernet 1/0/1, GigabitEthernet 1/0/2, and GigabitEthernet 1/0/3 on the chassis front panel.

4. Click **Apply**.

Configuration guidelines

When you configure a link aggregation group, follow these guidelines:

- In an aggregation group, t a Selected port must have the same port attributes and class-two configurations as the reference port. To keep these configurations consistent, you should configure the port manually.
- Choose a reference port from the member ports that are in up state and with the same class-two configurations as the aggregate interface. The candidate ports are sorted in the following order:
 - Full duplex/high speed
 - Full duplex/low speed
 - Half duplex/high speed
 - Half duplex/low speed

If two ports with the same duplex mode/speed pair are present, the one with the lower port number is chosen.

- Port attribute configuration includes the configuration of the port rate, duplex mode, and link state. For more information about class-two configurations, see "[Configuration classes](#)."
- To guarantee a successful static aggregation, make sure that the ports at the two ends of each link to be aggregated are in the same aggregation state. To guarantee a successful dynamic

228

- aggregation, make sure that the peer ports of the ports aggregated at one end are also aggregated. The two ends can automatically negotiate the aggregation state of each member port.
- Removing a Layer 2 aggregate interface also removes its aggregation group and causes all member ports to leave the aggregation group.

Configuring LLDP

Overview

In a heterogeneous network, a standard configuration exchange platform ensures that different types of network devices from different vendors can discover one another and exchange configuration for the sake of interoperability and management.

The Link Layer Discovery Protocol (LLDP) is specified in IEEE 802.1AB. The protocol operates on the data link layer to exchange device information between directly connected devices. With LLDP, a device sends local device information (including its major functions, management IP address, device ID, and port ID) as TLV (type, length, and value) triplets in LLDP Data Units (LLDPDUs) to the directly connected devices. At the same time, the device stores the device information received in LLDPDUs sent from the LLDP neighbors in a standard management information base (MIB). For more information about MIBs, see "[Configuring SNMP](#)." LLDP enables a network management system to quickly detect and identify Layer 2 network topology changes.

Basic concepts

LLDPDU formats

LLDP sends device information in LLDP data units (LLDPDUs). LLDPDUs are encapsulated in Ethernet II or Subnetwork Access Protocol (SNAP) frames.

1. LLDPDUs encapsulated in Ethernet II

Figure 201 LLDPDU encapsulated in Ethernet II

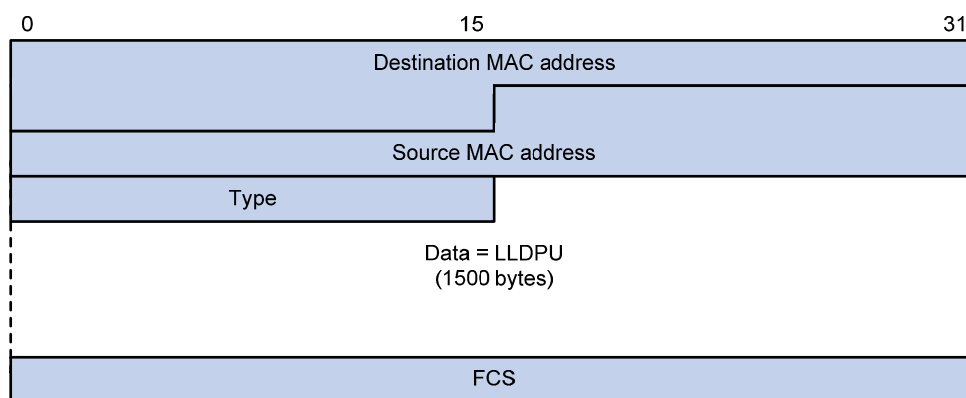

Table 70 Description of the fields in an Ethernet II encapsulated LLDPDU

Field	Description
Destination MAC address	MAC address to which the LLDPDU is advertised. It is fixed to 0x0180-C200-000E, a multicast MAC address.
Source MAC address	MAC address of the sending port.
Type	Ethernet type for the upper layer protocol. It is 0x88CC for LLDP.

Field	Description
Data	LLDP data.
FCS	Frame check sequence, a 32-bit CRC value used to determine the validity of the received Ethernet frame.

2. LLDPDUs encapsulated in SNAP

Figure 202 LLDPDU encapsulated in SNAP

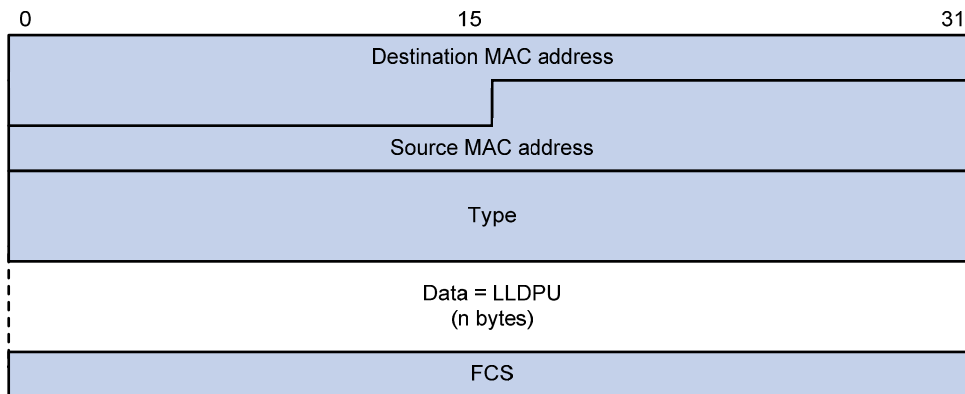

Table 71 Description of the fields in a SNAP-encapsulated LLDPDU

Field	Description
Destination MAC address	MAC address to which the LLDPDU is advertised. It is fixed to 0x0180-C200-000E, a multicast MAC address.
Source MAC address	MAC address of the sending port. If the port does not have a MAC address, the MAC address of the sending bridge is used.
Type	SNAP-encoded LLDP Ethernet type for the upper layer protocol. It is 0xAAAA-0300-0000-88CC for LLDP.
Data	LLDP data unit.
FCS	Frame check sequence, a 32-bit CRC value used to determine the validity of the received Ethernet frame.

LLDPDUs

LLDP uses LLDPDUs to exchange information. An LLDPDU comprises multiple type, length, and value (TLV) sequences, each carrying a type of device information, as shown in [Figure 203](#).

Figure 203 LLDPDU encapsulation format

An LLDPDU can carry up to 28 types of TLVs, of which the chassis ID TLV, port ID TLV, Time to Live (TTL) TLV, and end of LLDPDU TLV are mandatory TLVs that must be carried and other TLVs are optional.

TLVs

TLVs are type, length, and value sequences that carry information elements, where the type field identifies the type of information, the length field indicates the length of the information field in octets, and the value field contains the information itself.

LLDPDU TLVs include the following categories: basic management TLVs, organizationally (IEEE 802.1 and IEEE 802.3) specific TLVs, and LLDP-MED (media endpoint discovery) TLVs. Basic management TLVs are essential to device management. Organizationally specific TLVs and LLDP-MED TLVs are used for enhanced device management; they are defined by standardization or other organizations and are optional to LLDPDUs.

1. Basic management TLVs

Table 72 lists the basic management TLV types in use. Some of them must be included in every LLDPDU.

Table 72 Basic LLDP TLVs

Type	Description	Remarks
Chassis ID	Specifies the bridge MAC address of the sending device.	
Port ID	Specifies the ID of the sending port. If LLDP-MED TLVs are included in the LLDPDU, the port ID TLV carries the MAC address of the sending port or the bridge MAC in case the port does not have a MAC address. If no LLDP-MED TLVs are included, the port ID TLV carries the port name.	Mandatory
Time to Live	Specifies the life of the transmitted information on the receiving device.	
End of LLDPDU	Marks the end of the TLV sequence in the LLDPDU.	
Port Description	Specifies the port description of the sending port.	
System Name	Specifies the assigned name of the sending device.	
System Description	Specifies the description of the sending device.	
System Capabilities	Identifies the primary functions of the sending device and the primary functions that have been enabled.	Optional
Management Address	Specifies the management address used to reach higher level entities to assist discovery by network management, and the interface number and OID (object identifier) associated with the address.	

2. IEEE 802.1 organizationally specific TLVs

Table 73 IEEE 802.1 organizationally specific TLVs

Type	Description
Port VLAN ID	Specifies the port's VLAN identifier (PVID). An LLDPDU carries only one TLV of this type.
Port And Protocol VLAN ID	Indicates whether the device supports protocol VLANs and, if so, what VLAN IDs these protocols will be associated with. An LLDPDU can carry multiple different TLVs of this type.
VLAN Name	Specifies the textual name of any VLAN to which the port belongs. An LLDPDU can carry multiple different TLVs of this type.
Protocol Identity	Indicates protocols supported on the port. An LLDPDU can carry multiple different TLVs of this type.
DCBX	Data center bridging exchange protocol.

NOTE:

- HP devices only support receiving protocol identity TLVs.
 - Layer 3 Ethernet interfaces do not support IEEE 802.1 organizationally specific TLVs.
-

3. IEEE 802.3 organizationally specific TLVs**Table 74 IEEE 802.3 organizationally specific TLVs**

Type	Description
MAC/PHY Configuration/Status	Contains the rate and duplex capabilities of the sending port, support for auto negotiation, enabling status of auto negotiation, and the current rate and duplex mode.
Power Via MDI	Contains the power supply capability of the port, including the Power over Ethernet (PoE) type (Power Sourcing Equipment (PSE) or Powered Device (PD)), PoE mode, whether PSE power supply is supported, whether PSE power supply is enabled, and whether the PoE mode is controllable.
Link Aggregation	Indicates the support of the port for link aggregation, the aggregation capability of the port, and the aggregation status (or whether the link is in an aggregation).
Maximum Frame Size	Indicates the supported maximum frame size. It is now the Maximum Transmission Unit (MTU) of the port.
Power Stateful Control	Indicates the power state control configured on the sending port, including the power type of the PSE/PD, PoE sourcing/receiving priority, and PoE sourcing/receiving power.

NOTE:

The Power Stateful Control TLV is defined in IEEE P802.3at D1.0. The later versions no longer support this TLV. HP devices send this type of TLVs only after receiving them.

4. LLDP-MED TLVs

LLDP-MED TLVs provide multiple advanced applications for voice over IP (VoIP), such as basic configuration, network policy configuration, and address and directory management. LLDP-MED TLVs meet the voice device vendors' requirements for cost effectiveness, ease of deployment, and ease of management. In addition, LLDP-MED TLVs make deploying voice devices in Ethernet easier. LLDP-MED TLVs are shown in [Table 75](#).

Table 75 LLDP-MED TLVs

Type	Description
LLDP-MED Capabilities	Allows a network device to advertise the LLDP-MED TLVs that it supports.
Network Policy	Allows a network device or terminal device to advertise the VLAN ID of the specific port, the VLAN type, and the Layer 2 and Layer 3 priorities for specific applications.
Extended Power-via-MDI	Allows a network device or terminal device to advertise power supply capability. This TLV is an extension of the Power Via MDI TLV.
Hardware Revision	Allows a terminal device to advertise its hardware version.
Firmware Revision	Allows a terminal device to advertise its firmware version.

Type	Description
Software Revision	Allows a terminal device to advertise its software version.
Serial Number	Allows a terminal device to advertise its serial number.
Manufacturer Name	Allows a terminal device to advertise its vendor name.
Model Name	Allows a terminal device to advertise its model name.
Asset ID	Allows a terminal device to advertise its asset ID. The typical case is that the user specifies the asset ID for the endpoint to facilitate directory management and asset tracking.
Location Identification	Allows a network device to advertise the appropriate location identifier information for a terminal device to use in the context of location-based applications.

NOTE:

For more information about LLDPDU TLVs, see the IEEE standard (LLDP) 802.1AB-2005 and the LLDP-MED standard (ANSI/TIA-1057).

Management address

The management address of a device is used by the network management system to identify and manage the device for topology maintenance and network management. The management address is encapsulated in the management address TLV.

Operating modes of LLDP

LLDP can operate in one of the following modes:

- **TxRx mode**—A port in this mode can send and receive LLDPDUs.
- **Tx mode**—A port in this mode can only send LLDPDUs.
- **Rx mode**—A port in this mode can only receive LLDPDUs.
- **Disable mode**—A port in this mode cannot send or receive LLDPDUs.

Each time the LLDP operating mode of a port changes, its LLDP protocol state machine re-initializes. To prevent LLDP from being initialized too frequently at times of frequent operating mode change, an initialization delay, which is user configurable, is introduced. With this delay mechanism, a port must wait for the specified interval before it can initialize LLDP after the LLDP operating mode changes.

How LLDP works

Transmitting LLDPDUs

An LLDP-enabled port operating in TxRx mode or Tx mode sends LLDPDUs to its directly connected devices both periodically and when the local configuration changes. To prevent the network from being overwhelmed by LLDPDUs at times of frequent local device information change, an interval is introduced between two successive LLDPDUs.

This interval is shortened to 1 second in either of the following cases:

- A new neighbor is discovered. A new LLDPDU is received carrying device information new to the local device.

- The LLDP operating mode of the port changes from Disable/Rx to TxRx or Tx.

This is the fast sending mechanism of LLDP. With this mechanism, a specific number of LLDPDUs are sent successively at the 1-second interval to help LLDP neighbors discover the local device as soon as possible. Then, the normal LLDPDU transit interval resumes.

Receiving LLDPDUs

An LLDP-enabled port operating in TxRx mode or Rx mode checks the TLVs carried in every LLDPDU it receives for validity violation. If valid, the information is saved and an aging timer is set for it based on the time to live (TTL) TLV carried in the LLDPDU. If the TTL TLV is zero, the information is aged out immediately.

Compatibility of LLDP with CDP

You need to enable CDP compatibility for your device to work with Cisco IP phones.

As your LLDP-enabled device cannot recognize Cisco Discovery Protocol (CDP) packets, it does not respond to the requests of Cisco IP phones for the voice VLAN ID configured on the device. This can cause a requesting Cisco IP phone to send voice traffic untagged to your device, disabling your device to differentiate voice traffic from other types of traffic.

By configuring CDP compatibility, you can enable LLDP on your device to receive and recognize CDP packets from Cisco IP phones and respond with CDP packets carrying the voice VLAN configuration TLV for the IP phones to configure the voice VLAN automatically. The voice traffic is confined in the configured voice VLAN to be differentiated from other types of traffic.

CDP-compatible LLDP operates in one of the follows two modes:

- **TxRx**—CDP packets can be transmitted and received.
- **Disable**—CDP packets can neither be transmitted nor be received.

Protocols and standards

- IEEE 802.1AB-2005, *Station and Media Access Control Connectivity Discovery*
- ANSI/TIA-1057, *Link Layer Discovery Protocol for Media Endpoint Devices*

Recommended LLDP configuration procedure

Step	Remarks
1. Enabling LLDP on ports	<p>(Optional.)</p> <p>By default, LLDP is enabled on ports.</p> <p>Make sure that LLDP is also enabled globally, because LLDP can work on a port only when it is enabled both globally and on the port.</p>

Step	Remarks
	(Optional.) LLDP settings include LLDP operating mode, packet encapsulation, CDP compatibility, device information polling, trapping, and advertisable TLVs.
2. Setting LLDP parameters on ports	The default settings are as follows: <ul style="list-style-type: none"> • The LLDP operating mode is TxRx. • The encapsulation format is Ethernet II. • CDP compatibility is disabled. • Device information polling and trapping are disabled. • All TLVs except the Location Identification TLV are advertised.
3. Configuring LLDP globally	(Required.) By default, global LLDP is disabled. To enable LLDP to work on a port, enable LLDP both globally and on the port.
4. Displaying LLDP information for a port	(Optional.) You can display the local LLDP information, neighbor information, statistics, and status information of a port, where <ul style="list-style-type: none"> • The local LLDP information refers to the TLVs to be advertised by the local device to neighbors. • The neighbor information refers to the TLVs received from neighbors.
5. Displaying global LLDP information	(Optional.) You can display the local global LLDP information and statistics.
6. Displaying LLDP information received from LLDP neighbors	(Optional.) You can display the LLDP information received from LLDP neighbors.

Enabling LLDP on ports

1. Select **Network > LLDP** from the navigation tree.
By default, the **Port Setup** tab is displayed, as shown in [Figure 204](#). This tab displays the enabling status and operating mode of LLDP on a port.
2. Select one or more ports and click **Enable** beneath the port list to enable LLDP on them.
To disable LLDP on a port, select the port and click **Disable**.

Setting LLDP parameters on ports

The web interface allows you to set LLDP parameters for a single port and set LLDP parameters for multiple ports in batch.

Setting LLDP parameters for a single port

1. Select **Network** > **LLDP** from the navigation tree.
By default, the **Port Setup** tab is displayed.
2. Click the  icon for the port you are configuring.
On the page as shown in [Figure 205](#), the LLDP settings of the port are displayed.

Figure 205 Modifying LLDP settings on a port

Port Setup	Global Setup	Global Summary	Neighbor Summary
------------	--------------	----------------	------------------

<input checked="" type="checkbox"/> System Description	<input checked="" type="checkbox"/> System Name
<input checked="" type="checkbox"/> Management Address	<input type="text"/>
	<input type="text" value="Number"/>

+ Additional TLV Settings

3. Modify the LLDP parameters for the port as described in [Table 76](#).
4. Click **Apply**.
A progress dialog box appears.
5. Click **Close** on the progress dialog box when the progress dialog box prompts that the configuration succeeds.

Table 76 Configuration items

Item	Description
Interface Name	Displays the name of the port or ports you are configuring.
LLDP State	Displays the LLDP enabling status on the port you are configuring. This field is not available when you batch-configure ports.

Item	Description
Basic Settings	<p>Set the LLDP operating mode on the port or ports you are configuring. Available options include:</p> <ul style="list-style-type: none"> • TxRx—Sends and receives LLDPDUs. • Tx—Sends but not receives LLDPDUs. • Rx—Receives but not sends LLDPDUs. • Disable—Neither sends nor receives LLDPDUs.
	<p>Set the encapsulation for LLDPDUs. Available options include:</p> <ul style="list-style-type: none"> • ETHII—Encapsulates outgoing LLDPDUs in Ethernet II frames and processes an incoming LLDPDU only if its encapsulation is Ethernet II. • SNAP—Encapsulates outgoing LLDPDUs in Ethernet II frames and processes an incoming LLDPDU only if its encapsulation is Ethernet II. <p>NOTE: LLDP-CDP PDUs use only SNAP encapsulation.</p>
	<p>Set the CDP compatibility of LLDP. Available options include:</p> <ul style="list-style-type: none"> • Disable—Neither sends nor receives CDPDUs. • TxRx—Sends and receives CDPDUs
	<p>⚠ IMPORTANT: To enable LLDP to be compatible with CDP on the port, you must enable CDP compatibility on the Global Setup tab and set the CDP operating mode on the port to TxRx.</p>
	<p>Enable LLDP polling and set the polling interval. If no polling interval is set, LLDP polling is disabled. With the polling mechanism, LLDP periodically detects local configuration changes. If a configuration change is detected, an LLDPDU is sent to inform the LLDP neighbors of the change.</p>
Base TLV Settings	<p>Set the enable status of the LLDP trapping function on the port or ports. LLDP trapping is used to report to the network management station critical events such as new neighbor devices detected and link failures. NOTE: To avoid excessive traps from being sent when topology is instable, you can tune the minimum trap transit interval on the Global Setup tab.</p>
	<p>Port Description Select to include the port description TLV in transmitted LLDPDUs.</p>
	<p>System Capabilities Select to include the system capabilities TLV in transmitted LLDPDUs.</p>
	<p>System Description Select to include the system description TLV in transmitted LLDPDUs.</p>
	<p>System Name Select to include the system name TLV in transmitted LLDPDUs.</p>
	<p>Management Address Select to include the management address TLV in transmitted LLDPDUs and in addition, set the management address and its format (a numeric or character string in the TLV). If no management address is specified, the main IP address of the lowest VLAN carried on the port is used. If no main IP address is assigned to the VLAN, 127.0.0.1 is used.</p>

Item	Description
DOT1 TLV Setting	Port VLAN ID Select to include the PVID TLV in transmitted LLDPDUs.
	Protocol VLAN ID Select to include port and protocol VLAN ID TLVs in transmitted LLDPDUs and specify the VLAN IDs to be advertised. If no VLAN is specified, the lowest protocol VLAN ID is transmitted.
	VLAN Name Select to include VLAN name TLVs in transmitted LLDPDUs and specify the VLAN IDs to be advertised. If no VLAN is specified, the lowest VLAN carried on the port is advertised.
DOT3 TLV Setting	Link Aggregation Select to include the link aggregation TLV in transmitted LLDPDUs.
	MAC/PHY Configuration/Status Select to include the MAC/PHY configuration/status TLV in transmitted LLDPDUs.
	Maximum Frame Size Select to include the maximum frame size TLV in transmitted LLDPDUs.
	Power via MDI Select to include the power via MDI TLV and power stateful control TLV in transmitted LLDPDUs.
MED TLV Setting	LLDP-MED Capabilities Select to include the LLDP-MED capabilities TLV in transmitted LLDPDUs.
	Inventory Select to include the hardware revision TLV, firmware revision TLV, software revision TLV, serial number TLV, manufacturer name TLV, model name TLV and asset ID TLV in transmitted LLDPDUs.
	Network Policy Select to include the network policy TLV in transmitted LLDPDUs.
	Extended Power-via-MDI Capability Select to include the extended power-via-MDI TLV in transmitted LLDPDUs.
	Emergency Number Select to encode the emergency call number in the location identification TLV in transmitted LLDPDUs and set the emergency call number.
	Address Select Address to encode the civic address information of the network connectivity device in the location identification TLV in transmitted LLDPDUs. In addition, set the device type, which can be a DHCP server, switch or LLDP-MED endpoint, country code, and network device address.
	Network Device Address When you configure the network device address, select the address information type from the list, type the address information in the field below and click Add next to the field to add the information to the address information list below. To remove an address information entry, select the entry from the list, and click Delete . The civic address information can include language, province/state, country, city, street, house number, name, postal/zip code, room number, post office box, and if necessary, additional information.

Setting LLDP parameters for ports in batch

1. Select **Network** > **LLDP** from the navigation tree.
By default, the **Port Setup** tab is displayed.
2. Select one or multiple ports on the port list.

3. Click **Modify Selected** to enter the page for modifying these ports in batch.

Figure 206 Modifying LLDP settings on ports in batch

Port Setup	Global Setup	Global Summary	Neighbor Summary
Interface Name GigabitEthernet1/0/1 GigabitEthernet1/0/2 GigabitEthernet1/0/3

Trap Interval	5	Second(5-3600, Default = 5)	
Reinit Delay	2	Second(1-10, Default = 2)	
Tx Delay	2	Second(1-8192, Default = 2)	
Tx Interval	30	Second(5-32768, Default = 30)	
<input type="button" value="Apply"/>			

3. Set the global LLDP setup as described in [Table 77](#).
4. Click **Apply**.
A progress dialog box appears.
5. Click **Close** on the progress dialog box when the progress dialog box prompts that the configuration succeeds.

Table 77 Configuration items

Item	Description
LLDP Enable	Select from the list to enable or disable global LLDP.
CDP Compatibility	<p>Select from the list to enable or disable CDP compatibility of LLDP.</p> <p>! IMPORTANT:</p> <ul style="list-style-type: none"> To enable LLDP to be compatible with CDP on a port, you must set the CDP operating mode on the port to TxRx in addition to enabling CDP compatibility on the Global Setup tab. Because the maximum TTL allowed by CDP is 255 seconds, you must make sure that the product of the TTL multiplier and the LLDPDU transmit interval is less than 255 seconds for CDP-compatible LLDP to work correctly with Cisco IP phones.
Fast LLDPDU Count	Set the number of LLDPDUs sent each time fast LLDPDU transmission is triggered.

Item	Description
TTL Multiplier	<p>Set the TTL multiplier.</p> <p>The TTL TLV carried in an LLDPDU determines how long the device information carried in the LLDPDU can be saved on a recipient device. You can configure the TTL of locally sent LLDPDUs to determine how long information about the local device can be saved on a neighbor device by setting the TTL multiplier. The TTL is expressed as <i>TTL multiplier × LLDPDU transit interval</i>.</p> <p>NOTE:</p> <ul style="list-style-type: none"> • If the product of the TTL multiplier and the LLDPDU transmit interval is greater than 65535, the TTL carried in transmitted LLDPDUs takes 65535 seconds. • Because the maximum TTL allowed by CDP is 255 seconds, you must make sure that the product of the TTL multiplier and the LLDPDU transmit interval is less than 255 seconds for CDP-compatible LLDP to work correctly with Cisco IP phones.
Trap Interval	<p>Set the minimum interval for sending traps.</p> <p>With the LLDP trapping function enabled on a port, traps are sent out of the port to advertise the topology changes detected over the trap interval to neighbors. By tuning this interval, you can prevent excessive traps from being sent when topology is instable.</p>
Reinit Delay	<p>Set initialization delay for LLDP-enabled ports.</p> <p>Each time the LLDP operating mode of a port changes, its LLDP protocol state machine re-initializes. To prevent LLDP from being initialized too frequently at times of frequent operating mode change, initialization delay is introduced. With this delay mechanism, a port must wait for the specified interval before it can initialize LLDP after the LLDP operating mode changes.</p>
Tx Delay	<p>Set LLDPDU transmit delay.</p> <p>With LLDP enabled, a port advertises LLDPDUs to its neighbors both periodically and when the local configuration changes. To avoid excessive number of LLDPDUs caused by frequent local configuration changes, an LLDPDU transmit delay is introduced. After sending an LLDPDU, the port must wait for the specified interval before it can send another one.</p> <p>⚠ IMPORTANT:</p> <p>LLDPDU transmit delay must be less than the TTL to make sure that the LLDP neighbors can receive LLDPDUs to update information about the device you are configuring before it is aged out.</p>
Tx Interval	<p>Set the LLDPDU transmit interval.</p> <p>NOTE:</p> <p>If the product of the TTL multiplier and the LLDPDU transmit interval is greater than 65535, the TTL carried in transmitted LLDPDUs takes 65535 seconds. The likelihood exists that the LLDPDU transmit interval is greater than TTL. You should avoid the situation, because the LLDP neighbors will fail to receive LLDPDUs to update information about the device you are configuring before it is aged out.</p>

Displaying LLDP information for a port

1. Select **Network > LLDP** from the navigation tree.
By default, the **Port Setup** tab is displayed.
2. On the port list, click a port name to display its LLDP information at the lower half of the page.

By default, the Local Information tab is displayed, as shown in [Figure 208](#). [Table 78](#) describes the fields.

Figure 208 The Local Information tab

LLDP configuration examples

LLDP basic settings configuration example

Network requirements

As shown in Figure 214, configure LLDP on Switch A and Switch B so that the network management station (NMS) can determine the status of the link between Switch A and MED and the link between Switch A and Switch B.

Figure 214 Network diagram

Configuring Switch A

1. Enable LLDP on GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2. (Optional. By default, LLDP is enabled on Ethernet ports.)
2. Set the LLDP operating mode to Rx on GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2:
 - a. Select **Network > LLDP** from the navigation tree.
By default, the **Port Setup** tab is displayed.

- b. Select port GigabitEthernet1/0/1 and GigabitEthernet1/0/2.
- c. Click **Modify Selected**.

The page shown in Figure 216 appears.

Configuring Switch B

1. Enable LLDP on port GigabitEthernet 1/0/1. (Optional. By default, LLDP is enabled on Ethernet ports.)
2. Set the LLDP operating mode to Tx on GigabitEthernet 1/0/1:
 - a. Select **Network** > **LLDP** from the navigation tree.
By default, the **Port Setup** tab is displayed.
 - b. Click the  icon for port GigabitEthernet1/0/1.
The page shown in Figure 218 is displayed.
 - c. Select **Tx** from the **LLDP Operating Mode** list.
3. Click **Apply**.
A progress dialog box appears.
4. Click **Close** on the progress dialog box when the progress dialog box prompts that the configuration succeeds.

 - b. Select **Enable** from the **LLDP Enable** list.
6. Click **Apply**.
A progress dialog box appears.
7. Click **Close** on the progress dialog box when the progress dialog box prompts that the configuration succeeds.

Verifying the configuration

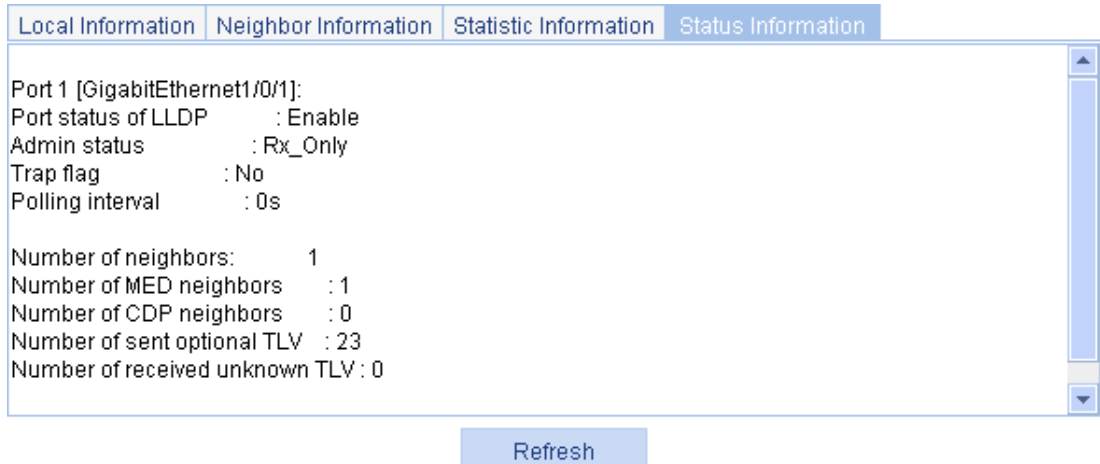

1. Display the status information of port GigabitEthernet1/0/1 on Switch A:
 - a. Select **Network** > **LLDP** from the navigation tree.

By default, the **Port Setup** tab is displayed.

- b. Click the **GigabitEthernet1/0/1** port name in the port list.
- c. Click the **Status Information** tab at the lower half of the page.

The output shows that port GigabitEthernet 1/0/1 is connected to an MED neighbor device.

Figure 219 Viewing the status of port GigabitEthernet 1/0/1

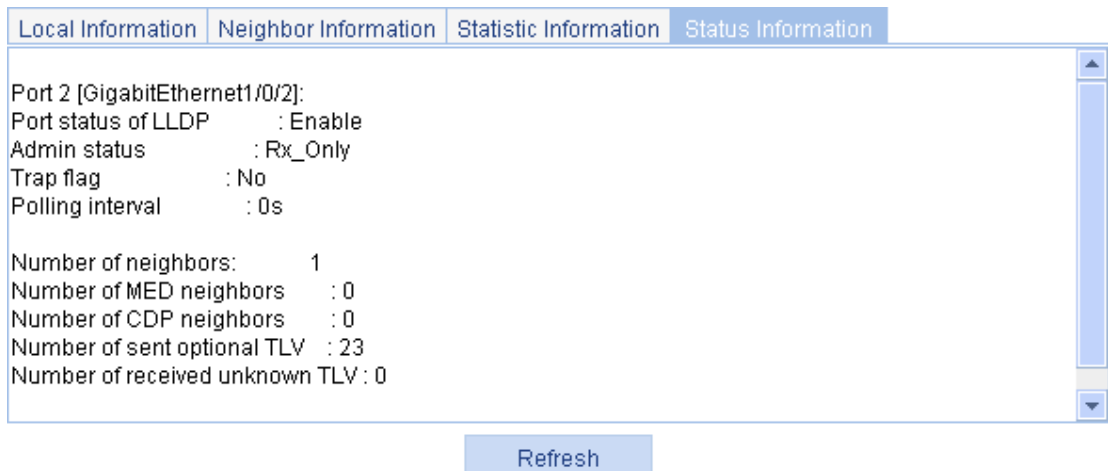

2. Display the status information of port GigabitEthernet1/0/2 on Switch A:

- a. Click the **GigabitEthernet1/0/2** port name in the port list.
- b. Click the **Status Information** tab at the lower half of the page.

The output shows that port GigabitEthernet 1/0/2 is connected to a non-MED neighbor device (Switch B).

Figure 220 Viewing the status of port GigabitEthernet 1/0/2

3. Tear down the link between Switch A and Switch B.
4. Click **Refresh** to display the status information of port GigabitEthernet1/0/2 on Switch A.
The updated status information of port GigabitEthernet 1/0/2 shows that no neighbor device is connected to the port.

CDP-compatible LLDP configuration example

Network requirements

As shown in [Figure 222](#), on Switch A, configure VLAN 2 as a voice VLAN and configure CDP-compatible LLDP to enable the Cisco IP phones to automatically configure the voice VLAN, confining their voice traffic within the voice VLAN to be separate from other types of traffic.

Figure 222 Network diagram

Configuring Switch A

1. Create VLAN 2:
 - a. Select **Network > VLAN** from the navigation tree.
 - b. Click **Create** to enter the page for creating VLANs.
 - c. Enter **2** in the **VLAN IDs** field.
 - d. Click **Create**.

Figure 223 Creating VLANs

Modify VLAN description (Note: you can do this later on the Modify VLAN page)

Modify the description of the selected VLAN:

ID	Description
<input type="text"/>	<input type="text" value=""/>

(1-32 Chars.)

2. Configure GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 as trunk ports:
 - a. Select **Device** > **Port Management** from the navigation tree.
 - b. Click the **Setup** tab to enter the page for configuring ports.
 - c. Select **Trunk** in the **Link Type** list.
 - d. Select port GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 from the chassis front panel.
 - e. Click **Apply**.

3. Configure the voice VLAN function on the two ports:
 - a. Select **Network** > **Voice VLAN** from the navigation tree.
 - b. Click the **Port Setup** tab to enter the page for configuring the voice VLAN function on ports.
 - c. Select **Auto** in the **Voice VLAN port mode** list, select **Enable** in the **Voice VLAN port state** list, enter the voice VLAN ID **2**, and select port GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 from the chassis front panel.
 - d. Click **Apply**.

Figure 225 Configuring the voice VLAN function on ports

The screenshot shows a network configuration page with tabs: Summary, Setup, Port Setup (selected), OUI Summary, OUI Add, and OUI Remove. In the Port Setup section, a red box highlights the following fields: Voice VLAN port mode (set to Auto), Voice VLAN port state (set to Enable), and Voice VLAN ID (set to 2, with a note *(2-4094)). Below these fields is a note: "Items marked with an asterisk(*) are required".

Under the "Select ports:" section, there is a visual representation of a switch port panel with 9 ports. Ports 1 and 2 are highlighted with a red box. Below the port panel are "Select All" and "Select None" buttons. Below that, a text box labeled "Ports selected for voice VLAN:" contains the text "GE1/0/1-GE1/0/2". At the bottom right, there are "Apply" and "Cancel" buttons, with the "Apply" button highlighted by a red box.

4. Enable LLDP on ports GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2. Skip this step if LLDP is enabled (the default).
5. Set both the LLDP operating mode and the CDP operating mode to TxRx on ports GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2:
 - a. Select **Network > LLDP** from the navigation tree.
By default, the **Port Setup** tab is displayed.
 - b. Select port GigabitEthernet1/0/1 and GigabitEthernet1/0/2.
 - c. Click **Modify Selected**.
The page shown in [Figure 227](#) is displayed.

Verifying the configuration

Display information about LLDP neighbors on Switch A after completing the configuration. You can see that Switch A has discovered the Cisco IP phones attached to ports GigabitEthernet1/0/1 and GigabitEthernet1/0/2 and obtained their device information.

LLDP configuration guidelines

When you configure LLDP, follow these guidelines:

- To make LLDP take effect, you must enable it both globally and at port level.
- To advertise LLDP-MED TLVs other than the LLDP-MED capabilities TLV, you must include the LLDP-MED capabilities TLV.
- To remove the LLDP-MED capabilities TLV, you must remove all other LLDP-MED TLVs.
- To remove the MAC/PHY configuration TLV, remove the LLDP-MED capabilities set TLV first.
- When the advertising of LLDP-MED capabilities TLV and MAC/PHY configuration/status TLV is disabled, if the LLDP-MED capabilities set TLV is included, the MAC/PHY configuration/status TLV is included automatically.
- When you configure LLDP settings for ports in batch, if you do not set the TLVs, each port uses its own TLV settings.

Configuring ARP

This chapter describes how to configure the Address Resolution Protocol (ARP).

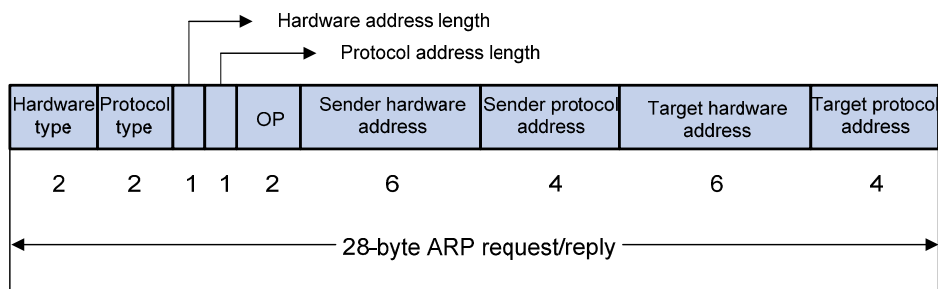

Overview

ARP resolves IP addresses into MAC addresses on Ethernet networks.

ARP message format

ARP messages are classified into ARP requests and ARP replies. Figure 229 shows the format of the ARP request/reply messages. Numbers in the figure refer to field lengths.

Figure 229 ARP message format

The following describe the fields in Figure 229:

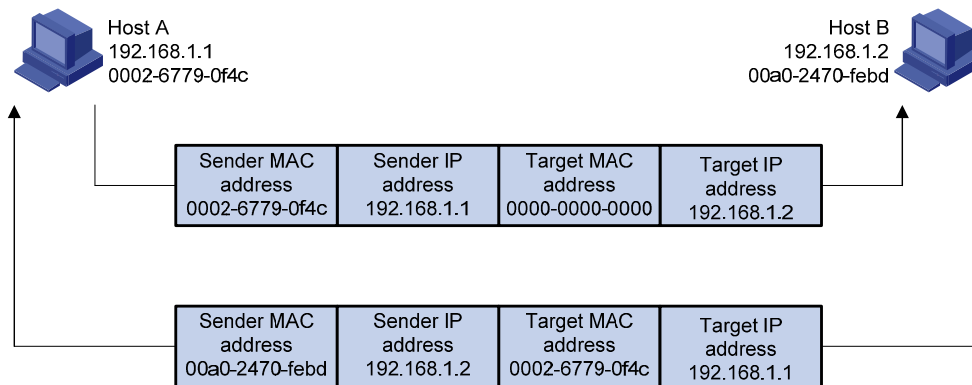

- **Hardware type**—The hardware address type. The value 1 represents Ethernet.
- **Protocol type**—The type of the protocol address to be mapped. The hexadecimal value 0x0800 represents IP.
- **Hardware address length and protocol address length**—Length, in bytes, of a hardware address and a protocol address, in bytes. For an Ethernet address, the value of the hardware address length field is 6. For an IPv4 address, the value of the protocol address length field is 4.
- **OP**—Operation code. The type of the ARP message. The value 1 represents an ARP request and 2 represents an ARP reply.
- **Sender hardware address**—Hardware address of the device sending the message.
- **Sender protocol address**—Protocol address of the device sending the message.
- **Target hardware address**—Hardware address of the device the message is being sent to.
- **Target protocol address**—Protocol address of the device the message is being sent to.

ARP operating mechanism

As shown in Figure 230, Host A and Host B are on the same subnet. Host A sends a packet to Host B as follows:

1. Host A looks in its ARP table to see whether there is an ARP entry for Host B. If yes, Host A uses the MAC address in the entry to encapsulate the IP packet into a data link layer frame. Then Host A sends the frame to Host B.
 2. If Host A finds no entry for Host B, Host A buffers the packet and broadcasts an ARP request using the following information:
 - **Source IP address and source MAC address**—Host A's own IP address and the MAC address.
 - **Target IP address**—Host B's IP address.
 - **Target MAC address**—An all-zero MAC address.
- Because the ARP request is a broadcast, all hosts on this subnet can receive the request, but only the requested host (Host B) will process the request.
3. Host B compares its own IP address with the target IP address in the ARP request. If they are the same, Host B:
 - a. Adds the sender IP address and sender MAC address to its ARP table.
 - b. Encapsulates its MAC address into an ARP reply.
 - c. Unicasts the ARP reply to Host A.
 4. After receiving the ARP reply, Host A:
 - a. Adds the MAC address of Host B to its ARP table.
 - b. Encapsulates the MAC address in the IP packet and sends it to Host B.

Figure 230 ARP address resolution process

If Host A and Host B are not on the same subnet:

1. Host A broadcasts an ARP request to the gateway. The target IP address in the ARP request is the IP address of the gateway.
2. After obtaining the MAC address of the gateway from an ARP reply, Host A sends the packet to the gateway.
3. If the gateway maintains an ARP entry for Host B, it forwards the packet to Host B directly. If not, the gateway broadcasts an ARP request, in which the target IP address is the IP address of Host B.
4. After the gateway gets the MAC address of Host B, it sends the packet to Host B.

ARP table

An ARP table contains dynamic and static ARP entries.

Dynamic ARP entry

ARP automatically creates and updates dynamic entries. A dynamic ARP entry is removed when its aging timer expires or the output interface goes down. In addition, a dynamic ARP entry can be overwritten by a static ARP entry.

Static ARP entry

A static ARP entry is manually configured and maintained. It does not age out and cannot be overwritten by any dynamic ARP entry.

Using static ARP entries enhances communication security. After a static ARP entry is specified, only a specific MAC address is associated with the specified IP address. Attack packets cannot modify the IP-to-MAC mapping. Thus, communications between devices are protected.

NOTE:

Usually ARP dynamically resolves IP addresses to MAC addresses, without manual intervention.

Gratuitous ARP

Gratuitous ARP packets

In a gratuitous ARP packet, the sender IP address and the target IP address are the IP address of the sending device.

A device sends a gratuitous ARP packet for either of the following purposes:

- Determine whether its IP address is already used by another device. If the IP address is already used, the device will be informed of the conflict by an ARP reply.
- Inform other devices of a MAC address change.

Gratuitous ARP packets learning

With this feature enabled, a device, upon receiving a gratuitous ARP packet, adds an ARP entry that contains the sender IP and MAC addresses in the packet to its ARP table. If the corresponding ARP entry exists, the device updates the ARP entry.

With this feature disabled, the device uses the received gratuitous ARP packets to update existing ARP entries only.

Configuring ARP entries

Displaying ARP entries

From the navigation tree, select **Network > ARP Management**. The **ARP Table** page appears, as shown in [Figure 231](#).

All ARP entries are displayed on the page.

Figure 231 ARP table configuration page

Port:	<input type="text"/>					
Items marked with an asterisk(*) are required						
			Apply	Back		

3. Configure the static ARP entry as described in [Table 81](#).
4. Click **Apply**.

Table 81 Configuration items

Item		Description
IP Address		Enter an IP address for the static ARP entry.
MAC Address		Enter a MAC address for the static ARP entry.
Advanced Options	VLAN ID	Enter a VLAN ID and specify a port for the static ARP entry.
	Port	<p>❗ IMPORTANT:</p> <p>The VLAN ID must be the ID of the VLAN that has already been created, and the port must belong to the VLAN. The corresponding VLAN interface must have been created.</p>

Removing ARP entries

1. From the navigation tree, select **Network > ARP Management**.
The **ARP Table** page appears, as shown in [Figure 231](#).
2. Remove ARP entries:
 - To remove specific ARP entries, select the boxes of target ARP entries, and click **Del Selected**.
 - To remove all static and dynamic ARP entries, click **Delete Static and Dynamic**.
 - To remove all static ARP entries, click **Delete Static**.
 - To remove all dynamic ARP entries, click **Delete Dynamic**.

Configuring gratuitous ARP

1. From the navigation tree, select **Network > ARP Management**.
2. Click the **Gratuitous ARP** tab.

Figure 233 Gratuitous ARP configuration page

Static ARP configuration example

Network Requirements

As shown in [Figure 234](#), hosts are connected to Switch A, and Switch A is connected to Router B through GigabitEthernet 1/0/1 in VLAN 100.

To ensure secure communications between Switch A and Router B, configure a static ARP entry on Switch A for Router B.

Figure 234 Network diagram

Configuring Switch A

1. Create VLAN 100:
 - a. From the navigation tree, select **Network > VLAN**.
 - b. Click the **Add** tab.
 - c. Enter **100** for **VLAN ID** and click **Create**.

Figure 235 Creating VLAN 100

Select VLAN	Create	Port Detail	Detail	Modify VLAN	Modify Port	Remove
-------------	--------	-------------	--------	-------------	-------------	--------

Create:

VLAN IDs: Example: 3, 5-10

ID	Description

Configuring ARP attack protection

Overview

Although ARP is easy to implement, it provides no security mechanism and thus is vulnerable to network attacks. The ARP detection feature enables access devices to block ARP packets from unauthorized clients to prevent user spoofing and gateway spoofing attacks.

ARP detection provides user validity check and ARP packet validity check.

User validity check

This feature does not check ARP packets received from ARP trusted ports, but it checks an ARP packets from ARP untrusted ports.

Upon receiving an ARP packet from an ARP untrusted interface, this feature compares the sender IP and MAC addresses of the ARP packet against the DHCP snooping entries, 802.1X security entries, and OUI MAC addresses.

If a match is found from those entries, the ARP packet is considered valid and is forwarded. If the sender MAC address of the received ARP packet is an OUI MAC address, the packet is considered valid.

If no match is found, the ARP packet is considered invalid and is discarded.

ARP packet validity check

This feature does not check ARP packets received from ARP trusted ports. It checks ARP packets received from ARP untrusted ports based on the following objects:

- **src-mac**—Checks whether the sender MAC address in the message body is identical to the source MAC address in the Ethernet header. If they are identical, the packet is forwarded; otherwise, the packet is discarded.
- **dst-mac**—Checks the target MAC address of ARP replies. If the target MAC address is all-zero, all-one, or inconsistent with the destination MAC address in the Ethernet header, the packet is considered invalid and discarded.
- **ip**—Checks the sender and target IP addresses of ARP replies, and the sender IP address of ARP requests. All-one or multicast IP addresses are considered invalid and the corresponding packets are discarded.

Configuring ARP detection

To check user validity, at least one among the DHCP snooping entries or 802.1X security entries is available. Otherwise, all ARP packets received from ARP untrusted ports are discarded, except for the ARP packets with an OUI MAC address as the sender MAC address when voice VLAN is enabled.

1. From the navigation tree, select **Network > ARP Anti-Attack**.

The ARP detection configuration page appears.

Configuring IGMP snooping

Overview

IGMP snooping runs on a Layer 2 switch as a multicast constraining mechanism to improve multicast forwarding efficiency. It creates Layer 2 multicast forwarding entries from IGMP packets that are exchanged between the hosts and the router.

As shown in [Figure 240](#), when IGMP snooping is not enabled, the Layer 2 switch floods multicast packets to all hosts. When IGMP snooping is enabled, the Layer 2 switch forwards multicast packets of known multicast groups to only the receivers of the multicast groups.

Figure 240 Multicast forwarding before and after IGMP snooping is enabled

Basic IGMP snooping concepts

This section describes the basic IGMP snooping concepts.

IGMP snooping related ports

As shown in [Figure 241](#), IGMP snooping runs on Switch A and Switch B, Host A and Host C are receivers in a multicast group.

Figure 241 IGMP snooping related ports

The following describes the ports involved in IGMP snooping:

- Router port**—Layer 3 multicast device-side port. Layer 3 multicast devices include designated routers and IGMP queriers. In [Figure 241](#), GigabitEthernet 1/0/1 of Switch A and GigabitEthernet 1/0/1 of Switch B are router ports. A switch records all its local router ports in its router port list. Do not confuse the "router port" in IGMP snooping with the "routed interface" commonly known as the "Layer 3 interface." The router port in IGMP snooping is the Layer 2 interface.
- Member port**—Multicast receiver-side port. In [Figure 241](#), GigabitEthernet 1/0/2 and GigabitEthernet 1/0/3 of Switch A and GigabitEthernet 1/0/2 of Switch B are member ports. A switch records all local member ports in the IGMP snooping forwarding table.

Unless otherwise specified, router ports and member ports in this document include both dynamic and static ports.

NOTE:

When IGMP snooping is enabled, all ports that receive PIM hello messages or IGMP general queries with the source addresses other than 0.0.0.0 are considered dynamic router ports.

Aging timers for dynamic ports in IGMP snooping

Timer	Description	Message received before the timer expires	Action after the timer expires
Dynamic router port aging timer	For each dynamic router port, the switch sets an aging timer. When the timer expires, the dynamic router port ages out.	IGMP general query with the source address other than 0.0.0.0 or PIM hello message.	The switch removes this port from its router port list.
Dynamic member port aging timer	When a port dynamically joins a multicast group, the switch sets an aging timer for the port. When the timer expires, the dynamic member port ages out.	IGMP membership report.	The switch removes this port from the IGMP snooping forwarding table.

NOTE:

In IGMP snooping, only dynamic ports age out. Static ports never age out.

How IGMP snooping works

The ports in this section are dynamic ports.

IGMP messages include general query, IGMP report, and leave message. An IGMP snooping-enabled switch performs differently depending on the message.

General query

The IGMP querier periodically sends IGMP general queries to all hosts and routers identified by the address **224.0.0.1** on the local subnet to determine whether any active multicast group members exist on the subnet.

After receiving an IGMP general query, the switch forwards the query to all ports in the VLAN except the receiving port. The switch also performs the following actions:

- If the receiving port is a dynamic router port in the router port list, the switch restarts the aging timer for the port.
- If the receiving port is not in the router port list, the switch adds the port as a dynamic router port and starts an aging timer for the port.

IGMP report

A host sends an IGMP report to the IGMP querier in the following circumstances:

- Responds to IGMP queries if the host is a multicast group member.
- Applies for a multicast group membership.

After receiving an IGMP report, the switch forwards it out of all the router ports in the VLAN and resolves the address of the reported multicast group. The switch also performs the following actions:

- If no forwarding entry matches the group address, the switch creates a forwarding entry for the group, adds the receiving port as a dynamic member port to the forwarding entry, and starts an aging timer for that port.
- If a forwarding entry matches the group address, but the receiving port is not in the forwarding entry for the group, the switch adds the port as a dynamic member port to the forwarding entry, and starts an aging timer for that port.
- If a forwarding entry matches the group address and the receiving port is in the forwarding entry for the group, the switch resets an aging timer for that port.

A switch does not forward an IGMP report through a non-router port. If the switch forwards a report through a member port, the IGMP report suppression mechanism running on hosts causes all attached hosts that monitor the reported multicast address to suppress their own reports. In this case, the switch cannot determine whether the reported multicast group still has active members attached to that port.

Leave message

An IGMPv1 host silently leaves a multicast group and the switch is not notified of the leave. However, because the host stops sending IGMP membership reports as soon as it leaves a multicast group, the switch removes the dynamic member port that connects to the host from the forwarding entry for the multicast group when the aging timer for the port expires.

An IGMPv2 or IGMPv3 host sends an IGMP leave message to the multicast router when it leaves a multicast group.

When the switch receives an IGMP leave group message on a member port, the switch first examines whether a forwarding entry matches the group address in the message, and, if a match is found, determines whether the forwarding entry for the group contains the dynamic member port.

- If no forwarding entry matches the group address, or if the forwarding entry does not contain the port, the switch directly discards the IGMP leave group message.
- If a forwarding entry matches the group address and the forwarding entry contains the port, the switch forwards the IGMP leave group message to all router ports in the VLAN. Because the switch does not know whether any other hosts attached to the port are still listening to that group address, the switch does not immediately remove the port from the forwarding entry for that group. Instead, the switch resets the aging timer for that port.

After receiving the IGMP leave message, the IGMP querier resolves the multicast group address in the message and sends an IGMP group-specific query to that multicast group through the port that received the leave message. After receiving the IGMP group-specific query, the switch forwards it through all its router ports in the VLAN and all member ports for that multicast group. The switch also performs one of the following actions for the port that received the IGMP leave message:

- If the port (assuming that it is a dynamic member port) receives any IGMP report in response to the group-specific query before its aging timer expires, it indicates that some host attached to the port is receiving or expecting to receive multicast data for that multicast group. The switch resets the aging timer of the port.
- If the port receives no IGMP report in response to the group-specific query before its aging timer expires, it indicates that no hosts attached to the port are still listening to that group address. The switch removes the port from the forwarding entry for the multicast group when the aging timer expires.

Protocols and standards

IGMP snooping configuration example

Network requirements

As shown in Figure 247, IGMPv2 runs on Router A and IGMPv2 snooping runs on Switch A. Router A acts as the IGMP querier.

Perform the configuration so that Host A can receive the multicast data destined for the multicast group **224.1.1.1**, and Switch A drops the unknown multicast data rather than flooding it in the VLAN.

Figure 247 Network diagram

Configuration procedure

Configuring Router A

Enable IP multicast routing, enable PIM-DM on each interface, and enable IGMP on Ethernet 1/1.
(Details not shown.)

Configuring Switch A

1. Create VLAN 100:
 - a. Select **Network** > **VLAN** from the navigation tree.
 - b. Click the **Create** tab.
 - c. Enter **100** as the VLAN ID.
 - d. Click **Apply**.

The output shows that GigabitEthernet 1/0/3 of Switch A is listening to multicast streams destined for the multicast group **224.1.1.1**.

Configuring MLD snooping

Overview

MLD snooping runs on a Layer 2 switch as an IPv6 multicast constraining mechanism to improve multicast forwarding efficiency. It creates Layer 2 multicast forwarding entries from MLD messages that are exchanged between the hosts and the router.

As shown in [Figure 254](#), when MLD snooping is not enabled, the Layer 2 switch floods IPv6 multicast packets to all hosts. When MLD snooping is enabled, the Layer 2 switch forwards multicast packets of known IPv6 multicast groups to only the receivers of the multicast groups.

Figure 254 IPv6 multicast forwarding before and after MLD snooping is enabled

Basic MLD snooping concepts

MLD snooping related ports

As shown in [Figure 255](#), MLD snooping runs on Switch A and Switch B. Host A and Host C are receivers in an IPv6 multicast group.

Figure 255 MLD snooping related ports

The following describes the ports involved in MLD snooping:

- Router port**—Layer 3 multicast device-side port. Layer 3 multicast devices include designated routers and MLD queriers. As shown in [Figure 255](#), GigabitEthernet 1/0/1 of Switch A and GigabitEthernet 1/0/1 of Switch B are router ports. A switch records all its local router ports in its router port list.
 Do not confuse the "router port" in MLD snooping with the "routed interface" commonly known as the "Layer 3 interface." The router port in MLD snooping is a Layer 2 interface.
- Member port**—Multicast receiver-side port. As shown in [Figure 255](#), GigabitEthernet 1/0/2 and GigabitEthernet 1/0/3 of Switch A and GigabitEthernet 1/0/2 of Switch B are member ports. A switch records all local member ports in its MLD snooping forwarding table.

Unless otherwise specified, router ports and member ports in this document include both dynamic and static ports.

NOTE:

When MLD snooping is enabled, all ports that receive IPv6 PIM hello messages or MLD general queries with source addresses other than 0::0 are considered dynamic router ports.

Aging timers for dynamic ports in MLD snooping

Timer	Description	Message received before the timer expires	Action after the timer expires
Dynamic router port aging timer	For each dynamic router port, the switch sets an aging timer. When the timer expires, the dynamic router port ages out.	MLD general query with the source address other than 0::0 or IPv6 PIM hello message.	The switch removes this port from its router port list.

Timer	Description	Message received before the timer expires	Action after the timer expires
Dynamic member port aging timer	When a port dynamically joins an IPv6 multicast group, the switch sets an aging timer for the port. When the timer expires, the dynamic member port ages out.	MLD membership report.	The switch removes this port from the MLD snooping forwarding table.

NOTE:

In MLD snooping, only dynamic ports age out. Static ports never age out.

How MLD snooping works

The ports in this section are dynamic ports.

MLD messages include general query, MLD report, and done message. An MLD snooping-enabled switch performs differently depending on the MLD message.

General query

The MLD querier periodically sends MLD general queries to all hosts and routers identified by the IPv6 address **FF02::1** on the local subnet to check whether any active IPv6 multicast group members exist on the subnet.

After receiving an MLD general query, the switch forwards the query to all ports in the VLAN except the receiving port. The switch also performs one of the following actions:

- If the receiving port is a dynamic router port in the router port list, the switch restarts the aging timer for the router port.
- If the receiving port is not in the router port list, the switch adds the port as a dynamic router port to the router port list and starts an aging timer for the port.

MLD report

A host sends an MLD report to the MLD querier for the following purposes:

- Responds to queries if the host is an IPv6 multicast group member.
- Applies for an IPv6 multicast group membership.

After receiving an MLD report, the switch forwards it through all the router ports in the VLAN and resolves the address of the reported IPv6 multicast group. The switch also performs one of the following actions:

- If no forwarding entry matches the IPv6 group address, the switch creates a forwarding entry for the group, adds the receiving port as a dynamic member port to the forwarding entry, and starts an aging timer for the port.
- If a forwarding entry matches the IPv6 group address, but the receiving port is not in the forwarding entry for the group, the switch adds the port as a dynamic member port to the forwarding entry, and starts an aging timer for the port.
- If a forwarding entry matches the IPv6 group address and the receiving port is in the forwarding entry for the group, the switch resets an aging timer for the port.

A switch does not forward an MLD report through a non-router port. If the switch forwards a report through a member port, the MLD report suppression mechanism causes all attached hosts that monitor the reported IPv6 multicast group address to suppress their own reports. In this case, the switch cannot determine whether the reported IPv6 multicast group still has active members attached to that port.

Done message

When a host leaves an IPv6 multicast group, the host sends an MLD done message to the multicast router. When the switch receives an MLD done message on a member port, the switch first examines whether a forwarding entry matches the IPv6 group address in the message, and, if a match is found, determines whether the forwarding entry contains the dynamic member port.

- If no forwarding entry matches the IPv6 multicast group address, or if the forwarding entry does not contain the port, the switch directly discards the MLD done message.
- If a forwarding entry matches the IPv6 multicast group address and contains the port, the switch forwards the MLD done message to all router ports in the VLAN. Because the switch does not know whether any other hosts attached to the port are still listening to that IPv6 multicast group address, the switch does not immediately remove the port from the forwarding entry for that group. Instead, the switch resets the aging timer for that port.

After receiving the MLD done message, the MLD querier resolves the IPv6 multicast group address in the message and sends an MLD multicast-address-specific query to that IPv6 multicast group through the port that received the MLD done message. After receiving the MLD multicast-address-specific query, the switch forwards it through all its router ports in the VLAN and all member ports for that IPv6 multicast group. The switch also performs one of the following actions for the port that received the MLD done message:

- If the port (assuming that it is a dynamic member port) receives any MLD report in response to the MLD multicast-address-specific query before its aging timer expires, it indicates that some host attached to the port is receiving or expecting to receive IPv6 multicast data for that IPv6 multicast group. The switch resets the aging timer for the port.
- If the port receives no MLD report in response to the MLD multicast-address-specific query before its aging timer expires, it indicates that no hosts attached to the port are still monitoring that IPv6 multicast group address. The switch removes the port from the forwarding entry for the IPv6 multicast group when the aging timer expires.

MLD snooping configuration example

Network requirements

As shown in [Figure 261](#), MLDv1 runs on Router A and MLDv1 snooping runs on Switch A. Router A acts as the MLD querier.

Perform the configuration so that Host A can receive the IPv6 multicast packets destined for the IPv6 multicast group **FF1E::101**, and Switch A drops the unknown IPv6 multicast packets rather than flooding them in the VLAN.

Figure 261 Network diagram

Configuration procedure

Configuring Router A

Enable IPv6 multicast routing, assign IPv6 address to each interface, enable IPv6 PIM-DM on each interface, and enable MLD on Ethernet 1/1. (Details not shown.)

Configuring Switch A

1. Create VLAN 100:
 - a. Select **Network** > **VLAN** from the navigation tree.
 - b. Click the **Create** tab.
 - c. Enter **100** as the VLAN ID.
 - d. Click **Apply**.

The output shows that GigabitEthernet 1/0/3 of Switch A is listening to multicast streams destined for the IPv6 multicast group **FF1E::101**.

Configuring IPv4 and IPv6 routing

The term "router" in this document refers to both routers and Layer 3 switches.

Overview

A router selects an appropriate route according to the destination address of a received packet and forwards the packet to the next router. The last router on the path is responsible for sending the packet to the destination host. Routing provides the path information that guides the forwarding of packets.

Routing table

A router selects optimal routes from the routing table, and sends them to the forwarding information base (FIB) table to guide packet forwarding. Each router maintains a routing table and a FIB table.

Routes discovered by different routing protocols are available in a routing table and they can be divided into the following categories by origin:

- **Direct routes**—Routes discovered by data link protocols, also known as "interface routes."
- **Static routes**—Manually configured routes. Static routes are easy to configure and require fewer system resources. They work well in small and stable networks, but cannot adjust to network changes, so you must manually configure the routes again whenever the network topology changes.
- **Dynamic routes**—Routes that are discovered dynamically by routing protocols.

Each entry in the FIB table specifies a physical interface that packets destined for a certain address should go out to reach the next hop—the next router—or the directly connected destination.

A route entry includes the following items:

- **Destination IP address**—Destination IP address or destination network.
- **Mask (IPv4)/prefix length (IPv6)**—Specifies, together with the destination address, the address of the destination network. A logical AND operation between the destination address and the network mask/prefix length yields the address of the destination network.
- **Preference**—Routes to the same destination might be discovered by various routing protocols or manually configured, and routing protocols and static routes have different preferences configured. The route with the highest preference (the smallest value) is optimal.
- **Outbound interface**—Specifies the interface through which a matching IP packet is to be forwarded.
- **Next hop**—Specifies the address of the next hop router on the path.

Static route

Static routes are manually configured. If a network's topology is simple, you only need to configure static routes for the network to work correctly.

Static routes cannot adapt to network topology changes. If a fault or a topological change occurs in the network, the network administrator must modify the static routes manually.

Default route

A default route is used to forward packets that do not match any specific routing entry in the routing table.

Without a default route, a packet that does not match any routing entries is discarded and an Internet Control Message Protocol (ICMP) destination-unreachable packet is sent to the source.

You can configure default routes in the Web interface in the following ways:

- Configure an IPv4 static default route and specify both its destination IP address and mask as 0.0.0.0.
- Configure an IPv6 static default route and specify both its destination IP address and prefix as ::/0.

Displaying the IPv4 active route table

Select **Network > IPv4 Routing** from the navigation tree to enter the page.

3. Create an IPv4 static route as described in [Table 91](#).
4. Click **Apply**.

Table 91 Configuration items

Item	Description
Destination IP Address	Enter the destination host or network IP address in dotted decimal notation.
Mask	Enter the mask of the destination IP address. You can enter a mask length or a mask in dotted decimal notation.

Item	Description
Preference	Set a preference value for the static route. The smaller the number, the higher the preference. For example, specifying the same preference for multiple static routes to the same destination enables load sharing on the routes. Specifying different preferences enables route backup.
Next Hop	Enter the next hop IP address in dotted decimal notation.
Interface	Select the output interface. You can select any available Layer 3 interface, for example, a virtual interface, of the device. If you select NULL 0, the destination IP address is unreachable.

Displaying the IPv6 active route table

Select **Network > IPv6 Routing** from the navigation tree to enter the page.

3. Create an IPv6 static route as described in [Table 93](#).
4. Click **Apply**.

Table 93 Configuration items

Item	Description
Destination IP Address	Enter the destination host or network IP address, in the X:X::X:X format. The 128-bit destination IPv6 address is a hexadecimal address with eight parts separated by colons (:). Each part is represented by a 4-digit hexadecimal integer.
Prefix Length	Enter or select the prefix length of the destination IPv6 address.

Item	Description
Preference	Set a preference value for the static route. The smaller the number, the higher the preference. For example, specifying the same preference for multiple static routes to the same destination enables load sharing on the routes. Specifying different priorities for them enables route backup.
Next Hop	Enter the next hop address, in the same format as the destination IP address.
Interface	Select the output interface. You can select any available Layer 3 interface, for example, a virtual interface, of the device. If you select NULL 0, the destination IPv6 address is unreachable.

IPv4 static route configuration example

Network requirements

As shown in [Figure 272](#), configure IPv4 static routes on Switch A, Switch B, and Switch C for any two hosts to communicate with each other.

Figure 272 Network diagram

Configuration considerations

On Switch A, configure a default route with Switch B as the next hop.

On Switch B, configure one static route with Switch A as the next hop and the other with Switch C as the next hop.

On Switch C, configure a default route with Switch B as the next hop.

Configuration procedure

- Configure a default route to Switch B on Switch A:
 - Select **Network > IPv4 Routing** from the navigation tree of Switch A.
 - Click the **Create** tab.
 - Enter **0.0.0.0** for **Destination IP Address**, **0** for **Mask**, and **1.1.4.2** for **Next Hop**.
 - Click **Apply**.

Figure 273 Configuring a default route

Summary	Create	Remove

Verifying the configuration

1. Display the routing table.

Enter the IPv4 route page of Switch A, Switch B, and Switch C to verify that the newly configured static routes are displayed as active routes on the page.

2. Ping Host C from Host A (assuming both hosts run Windows XP):

```
C:\Documents and Settings\Administrator>ping 1.1.3.2
```

```
Pinging 1.1.3.2 with 32 bytes of data:
```

```
Reply from 1.1.3.2: bytes=32 time=1ms TTL=128
```

```
Reply from 1.1.3.2: bytes=32 time=1ms TTL=128
```

```
Reply from 1.1.3.2: bytes=32 time=1ms TTL=128
```

```
Reply from 1.1.3.2: bytes=32 time=1ms TTL=128
```

```
Ping statistics for 1.1.3.2:
```

```
Packets: Sent = 4, Received = 4, Lost = 0 (0% loss),
```

```
Approximate round trip times in milli-seconds:
```

```
Minimum = 1ms, Maximum = 1ms, Average = 1ms
```

IPv6 static route configuration example

Network requirements

As shown in Figure 276, configure IPv6 static routes on Switch A, Switch B, and Switch C for any two hosts to communicate with each other.

Figure 276 Network diagram

Configuration considerations

On Switch A, configure a default route with Switch B as the next hop.

On Switch B, configure one static route with Switch A as the next hop and the other with Switch C as the next hop.

On Switch C, configure a default route with Switch B as the next hop.

Configuration procedure

1. Configure a default route to Switch B on Switch A:
 - a. Select **Network > IPv6 Routing** from the navigation tree of Switch A.
 - b. Click the **Create** tab.
 - c. Enter **::** for **Destination IP Address**, select **0** from the **Prefix Length** list, and enter **4::2** for **Next Hop**.
 - d. Click **Apply**.

  5 packet(s) transmitted
  5 packet(s) received
```

0.00% packet loss
round-trip min/avg/max = 62/62/63 ms

Configuration guidelines

When you configure a static route, follow these guidelines:

- If you do not specify the preference, the default preference will be used. Reconfiguration of the default preference applies only to newly created static routes. The Web interface does not support configuration of the default preference.
- If you specify the next hop address first and then configure it as the IP address of a local interface, such as a VLAN interface, the static route does not take effect.
- When you specify the output interface, note the following:
 - If the output interface is Null 0, no next hop address is required.
 - If the output interface is a broadcast interface (such as a VLAN interface), which might have multiple next hops, you must specify the output interface and the next hop at the same time.
- You can delete only IPv4 and IPv6 static routes on the **Remove** tab.

IPv6 management

IPv6, also called IP next generation (IPng), was designed by the IETF as the successor to IPv4. One significant difference between IPv6 and IPv4 is that IPv6 increases the IP address size from 32 bits to 128 bits.

To configure basic IPv6 settings, enable the IPv6 service function first.

Enabling IPv6 service

1. From the navigation tree, select **Network > IPv6 Management**.
2. On the **IPv6 Service** tab, select **Enable**.

Figure 280 Enabling IPv6 service

DHCP overview

The Dynamic Host Configuration Protocol (DHCP) provides a framework to assign configuration information to network devices.

DHCP uses the client-server model. [Figure 281](#) shows a typical DHCP application.

A DHCP client can obtain an IP address and other configuration parameters from a DHCP server on another subnet through a DHCP relay agent. For more information about the DHCP relay agent, see "[Figure 281](#)." You can enable the DHCP client on an interface. For more information about the DHCP client configuration, see "[Configuring VLAN interfaces](#)."

Figure 281 A typical DHCP application

DHCP address allocation

Allocation mechanisms

DHCP supports the following mechanisms for IP address allocation:

- **Static allocation**—The network administrator assigns an IP address to a client like a WWW server, and DHCP conveys the assigned address to the client.
- **Automatic allocation**—DHCP assigns a permanent IP address to a client.
- **Dynamic allocation**—DHCP assigns an IP address to a client for a limited period of time, which is called a lease. Most DHCP clients obtain their addresses in this way.

Dynamic IP address allocation process

Figure 282 Dynamic IP address allocation process

1. The client broadcasts a DHCP-DISCOVER message to locate a DHCP server.
2. A DHCP server offers configuration parameters such as an IP address to the client in a DHCP-OFFER message. The sending mode of the DHCP-OFFER is determined by the flag field in the DHCP-DISCOVER message. For more information about the DHCP message format, see ["DHCP message format."](#)
3. If several DHCP servers send offers to the client, the client accepts the first received offer, and broadcasts it in a DHCP-REQUEST message to request the IP address formally. IP addresses offered by other DHCP servers are still assignable to other clients.
4. All DHCP servers receive the DHCP-REQUEST message, but only the server from which the client accepts the offered IP address returns a DHCP-ACK message to the client, confirming that the IP address has been allocated to the client, or a DHCP-NAK unicast message, denying the IP address allocation.

After the client receives the DHCP-ACK message, it broadcasts a gratuitous ARP packet to verify whether the IP address assigned by the server is in use. If the client receives no response within the specified time, the client uses this IP address. Otherwise, the client sends a DHCP-DECLINE message to the server and requests an IP address again.

IP address lease extension

The dynamically assigned IP address has a lease. When the lease expires, the DHCP server reclaims the IP address. To continue using the IP address, the client must extend the lease duration.

When half of the lease duration elapses, the DHCP client sends a DHCP-REQUEST unicast to the DHCP server to extend the lease. Depending on availability of the IP address, the DHCP server returns a DHCP-ACK unicast confirming that the client's lease duration has been extended, or a DHCP-NAK unicast denying the request.

If the client receives no reply, it will broadcast another DHCP-REQUEST message for lease extension when seven eighths of the lease duration elapses. Again, depending on the availability of the IP address, the DHCP server returns either a DHCP-ACK unicast confirming that the client's lease duration has been extended, or a DHCP-NAK unicast denying the request.

DHCP message format

Figure 283 gives the DHCP message format, which is based on the BOOTP message format and involves eight types. These types of messages have the same format except that some fields have different values. The numbers in parentheses indicate the size of each field in bytes.

Figure 283 DHCP message format

0	7	15	23	31
op (1)	htype (1)	hlen (1)	hops (1)	
xid (4)				
secs (2)		flags (2)		
ciaddr (4)				
yiaddr (4)				
siaddr (4)				
giaddr (4)				
chaddr (16)				
sname (64)				
file (128)				
options (variable)				

- **op**—Message type defined in option field. 1 = REQUEST, 2 = REPLY
- **htype, hlen**—Hardware address type and length of a DHCP client.
- **hops**—Number of relay agents a request message traveled.
- **xid**—Transaction ID, a random number chosen by the client to identify an IP address allocation.
- **secs**—Filled in by the client, the number of seconds elapsed since the client began address acquisition or renewal process. Currently this field is reserved and set to 0.
- **flags**—The leftmost bit is defined as the BROADCAST (B) flag. If this flag is set to 0, the DHCP server sent a reply back by unicast; if this flag is set to 1, the DHCP server sent a reply back by broadcast. The remaining bits of the flags field are reserved for future use.
- **ciaddr**—Client IP address.
- **yiaddr**—"Your" (client) IP address, assigned by the server.
- **siaddr**—Server IP address, from which the clients obtained configuration parameters.
- **giaddr**—IP address of the first relay agent a request message traveled.
- **chaddr**—Client hardware address.
- **sname**—Server host name, from which the client obtained configuration parameters.
- **file**—Bootfile name and path information, defined by the server to the client.
- **options**—Optional parameters field that is variable in length, which includes the message type, lease, domain name server IP address, and WINS IP address.

DHCP options

DHCP uses the same message format as BOOTP, but DHCP uses the Option field to carry information for dynamic address allocation and to provide additional configuration information to clients.

Figure 284 DHCP option format

Common DHCP options

Common DHCP options:

- **Option 3**—Router option. It specifies the gateway IP address to be assigned to the client.
- **Option 6**—DNS server option. It specifies the DNS server IP address to be assigned to the client.
- **Option 33**—Static route option. It specifies a list of classful static routes (the destination addresses in these static routes are classful) that a client should add to its routing table. If both Option 33 and Option 121 exist, Option 33 is ignored.
- **Option 51**—IP address lease option.
- **Option 53**—DHCP message type option. It identifies the type of the DHCP message.
- **Option 55**—Parameter request list option. It is used by a DHCP client to request specified configuration parameters. The option contains values that correspond to the parameters requested by the client.
- **Option 60**—Vendor class identifier option. A client uses this option to identify the vendor to which it belongs. With this option, the DHCP server can determine the vendor a client belongs to and assign an IP address within a specific range.
- **Option 66**—TFTP server name option. It specifies a TFTP server to be assigned to the client.
- **Option 67**—Bootfile name option. It specifies the bootfile name to be assigned to the client.
- **Option 121**—Classless route option. It specifies a list of classless static routes (the destination addresses in these static routes are classless) that the requesting client should add to its routing table. If both Option 33 and Option 121 exist, Option 33 is ignored.
- **Option 150**—TFTP server IP address option. It specifies the TFTP server IP address to be assigned to the client.

For more information about DHCP options, see RFC 2132 and RFC 3442.

Relay agent option (Option 82)

Some options, such as Option 82, have no unified definitions in RFC 2132.

Option 82 is the relay agent option. It records the location information about the DHCP client. When a DHCP relay agent or DHCP snooping device receives a client's request, it adds Option 82 to the request message before forwarding the message to the server.

The administrator can locate the DHCP client to further implement security control and accounting. The Option 82 supporting server can also use such information to define individual assignment policies of IP address and other parameters for the clients.

Option 82 can include at most 255 sub-options and must have at least one sub-option. Option 82 supports two sub-options: sub-option 1 (Circuit ID) and sub-option 2 (Remote ID).

Option 82 has no unified definition. Its padding formats vary with vendors.

By default, the normal padding format is used on the device. You can specify the code type for the sub-options as ASCII or HEX. The padding contents for sub-options in the normal padding format are as follows:

- **Sub-option 1**—Contains the VLAN ID and interface number of the interface that received the client's request. The following figure gives its format. The value of the sub-option type is 1, and that of the circuit ID type is 0.

Figure 285 Sub-option 1 in normal padding format

- **Sub-option 2**—Contains the MAC address of the DHCP relay agent interface or the MAC address of the DHCP snooping device that received the client's request. The following figure gives its format. The value of the sub-option type is 2, and that of the remote ID type is 0.

Figure 286 Sub-option 2 in normal padding format

Protocols and standards

- RFC 3046, *DHCP Relay Agent Information Option*
- RFC 3442, *The Classless Static Route Option for Dynamic Host Configuration Protocol (DHCP) version 4*.

Configuring DHCP relay agent

Overview

The DHCP relay agent enables clients to get IP addresses from a DHCP server on another subnet. This feature avoids deploying a DHCP server for each subnet to centralize management and reduce investment. [Figure 287](#) shows a typical application of the DHCP relay agent.

Figure 287 DHCP relay agent application

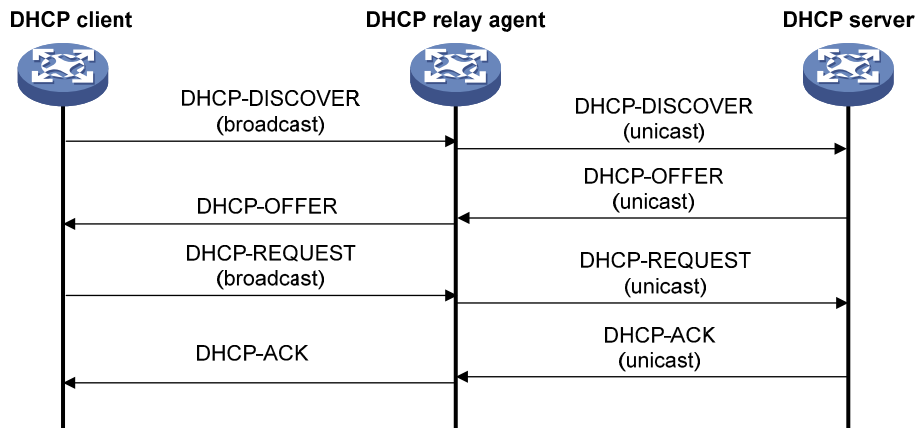

Operation

No matter whether a relay agent exists or not, the DHCP server and client interact with each other in the same way (see "[DHCP overview](#)"). For more information about DHCP packet exchange, see "[Dynamic IP address allocation process](#)."

The following describes the forwarding process on the DHCP relay agent:

1. After receiving a DHCP-DISCOVER or DHCP-REQUEST broadcast message from a DHCP client, the DHCP relay agent fills the **giaddr** field of the message with its IP address and forwards the message to the designated DHCP server in unicast mode.
2. Based on the **giaddr** field, the DHCP server returns an IP address and other configuration parameters in a response.
3. The relay agent conveys the response to the client.

Figure 288 DHCP relay agent operation

Recommended configuration procedure

Step	Remarks
1. Enabling DHCP and configuring advanced parameters for the DHCP relay agent	<p>(Required)</p> <p>Enable DHCP globally and configure advanced DHCP parameters. By default, global DHCP is disabled.</p>
2. Creating a DHCP server group	<p>(Required)</p> <p>To improve reliability, you can specify several DHCP servers as a group on the DHCP relay agent and correlate a relay agent interface with the server group. When the interface receives requesting messages from clients, the relay agent will forward them to all the DHCP servers of the group.</p>
3. Enabling the DHCP relay agent on an interface	<p>(Required)</p> <p>Enable the DHCP relay agent on an interface, and correlate the interface with a DHCP server group.</p> <p>With DHCP enabled, interfaces operate in the DHCP server mode by default.</p> <p>! IMPORTANT:</p> <p>The DHCP relay agent works on interfaces with IP addresses manually configured only.</p>
4. Configuring and displaying clients' IP-to-MAC bindings	<p>(Optional)</p> <p>Create a static IP-to-MAC binding, and view static and dynamic bindings.</p> <p>The DHCP relay agent can dynamically record clients' IP-to-MAC bindings after clients get IP addresses. It also supports static bindings, that is, you can manually configure IP-to-MAC bindings on the DHCP relay agent, so that users can access external network using fixed IP addresses.</p> <p>By default, no static binding is created.</p>

Enabling DHCP and configuring advanced parameters for the DHCP relay agent

1. Select **Network > DHCP** from the navigation tree to enter the **DHCP Relay** page.
2. Click **Display Advanced Configuration** to expand the advanced DHCP relay agent configuration area.

Figure 289 DHCP relay agent configuration page

User Information

User Information

3. Enable DHCP service and configure advanced parameters for DHCP relay agent as described in [Table 94](#).
4. Click **Apply**.

Table 94 Configuration items

Item	Description
DHCP Service	Enable or disable global DHCP.
Unauthorized Server Detect	<p>Enable or disable unauthorized DHCP server detection.</p> <p>There are unauthorized DHCP servers on networks, which reply DHCP clients with wrong IP addresses.</p> <p>With this feature enabled, upon receiving a DHCP request, the DHCP relay agent will record the IP address of any DHCP server that assigned an IP address to the DHCP client and the receiving interface. The administrator can use this information to check out DHCP unauthorized servers. The device puts a record once for each DHCP server. The administrator needs to find unauthorized DHCP servers from the log information. After the information of recorded DHCP servers is cleared, the relay agent will re-record server information following this mechanism.</p>
Dynamic Bindings Refresh	<p>Enable or disable periodic refresh of dynamic client entries, and set the refresh interval.</p> <p>A DHCP client sends a DHCP-RELEASE unicast message to the DHCP server through the DHCP relay agent to relinquish its IP address. In this case the DHCP relay agent simply conveys the message to the DHCP server, thus it does not remove the IP address from dynamic client entries. To solve this problem, the periodic refresh of dynamic client entries feature is introduced.</p>
Track Timer Interval	<p>With this feature, the DHCP relay agent uses the IP address of a client and the MAC address of the DHCP relay agent interface to periodically send a DHCP-REQUEST message to the DHCP server.</p> <ul style="list-style-type: none"> If the server returns a DHCP-ACK message or does not return any message within a specified interval, which means that the IP address is assignable now, the DHCP relay agent will age out the client entry. If the server returns a DHCP-NAK message, which means the IP address is still in use, the relay agent will not age it out. <p>Note that if the Auto option is selected, the refresh interval is calculated by the relay agent according to the number of client entries.</p>

Creating a DHCP server group

1. Select **Network > DHCP** from the navigation tree to enter the **DHCP Relay** page shown in [Figure 289](#).
2. In the **Server Group** area, click **Add** to enter the server group configuration page.

Figure 290 Creating a server group

The screenshot shows the DHCP Relay configuration interface. At the top, there are two tabs: 'DHCP Relay' (selected) and 'DHCP Snooping'. Below the tabs, there are two input fields: 'Server Group ID' and 'IP Address'. Both fields have an asterisk (*) next to them, indicating they are required. The 'Server Group ID' field also has a range '(0-19)' next to it. Below the input fields, there is a note: 'Items marked with an asterisk(*) are required'. At the bottom right, there are two buttons: 'Apply' and 'Cancel'.

3. Configure the DHCP server group as described in [Table 95](#).

4. Click **Apply**.

Table 95 Configuration items

Item	Description
Server Group ID	Enter the ID of a DHCP server group. You can create up to 20 DHCP server groups.
IP Address	Enter the IP address of a server in the DHCP server group. The server IP address cannot be on the same subnet as the IP address of the DHCP relay agent; otherwise, the client cannot obtain an IP address.

Enabling the DHCP relay agent on an interface

1. Select **Network > DHCP** from the navigation tree to enter the **DHCP Relay** page shown in [Figure 289](#).
2. In the **Interface Config** area, click the  icon for a specific interface.

Figure 291 Configuring a DHCP relay agent interface

3. Configure the DHCP relay agent on the interface as shown in [Table 96](#).
4. Click **Apply**.

Table 96 Configuration items

Item	Description
Interface Name	Displays the name of a specific interface.
DHCP Relay	Enable or disable the DHCP relay agent on the interface. If the DHCP relay agent is disabled, the DHCP server is enabled on the interface.
Address Match Check	Enable or disable IP address check. With this function enabled, the DHCP relay agent checks whether a requesting client's IP and MAC addresses match a binding (dynamic or static) on the DHCP relay agent. If not, the client cannot access outside networks through the DHCP relay agent. This prevents invalid IP address configuration.
Server Group ID	Correlate the interface with a DHCP server group. A DHCP server group can be correlated with multiple interfaces.

Configuring and displaying clients' IP-to-MAC bindings

1. Select **Network** > **DHCP** from the navigation tree to enter the **DHCP Relay** page shown in [Figure 289](#).
2. In the **User Information** area, click **User Information** to view static and dynamic bindings.

Figure 292 Displaying clients' IP-to-MAC bindings

The screenshot shows the DHCP Relay configuration page. At the top, there are tabs for 'DHCP Relay' and 'DHCP Snooping'. Below the tabs is a search bar with a magnifying glass icon, a dropdown menu set to 'IP Address', a 'Search' button, and a link to 'Advanced Search'. Below the search bar is a table with the following data:

IP Address	MAC Address	Type	Interface Name	Operation
1.1.1.2	00e0-1234-5678	Static	Vlan-interface1	

Below the table are four buttons: 'Add', 'Return', 'Refresh', and 'Reset'.

3. Click **Add** to enter the page for creating a static IP-to-MAC binding.

Figure 293 Creating a static IP-to-MAC binding

The screenshot shows the page for creating a static IP-to-MAC binding. At the top, there are tabs for 'DHCP Relay' and 'DHCP Snooping'. Below the tabs are three input fields: 'IP Address' with a red asterisk, 'MAC Address' with a red asterisk and '(H-H-H)' in parentheses, and 'Interface Name' with a dropdown arrow. Below the input fields is a note: 'Items marked with an asterisk(*) are required'. At the bottom are two buttons: 'Apply' and 'Cancel'.

4. Configure the static IP-to-MAC binding as described in [Table 97](#).
5. Click **Apply**.

Table 97 Configuration items

Item	Description
IP Address	Enter the IP address of a DHCP client.
MAC Address	Enter the MAC address of the DHCP client.
Interface Name	Select the Layer 3 interface connected with the DHCP client. ! IMPORTANT: The interface of a static binding entry must be configured as a DHCP relay agent; otherwise, address entry conflicts might occur.

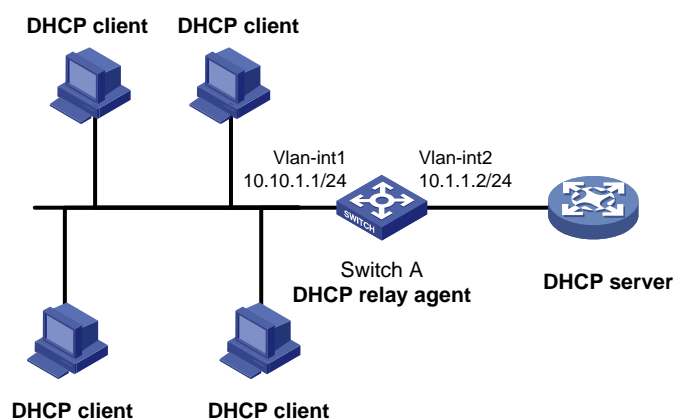

DHCP relay agent configuration example

Network requirements

As shown in [Figure 294](#), VLAN-interface 1 on the DHCP relay agent (Switch A) connects to the network where DHCP clients reside. VLAN-interface 2 is connected to the DHCP server whose IP address is 10.1.1.1/24.

The switch forwards messages between DHCP clients and the DHCP server.

Figure 294 Network diagram

Configuring Switch A

1. Enable DHCP:
 - a. Select **Network** > **DHCP** from the navigation tree to enter the **DHCP Relay** page.
 - b. Select the **Enable** option next to **DHCP Service**.
 - c. Click **Apply**.

IP Address 10.1.1.1 *

Items marked with an asterisk(*) are required

Apply Cancel

3. Enable the DHCP relay agent on VLAN-interface 1:
 - a. In the **Interface Config** field, click the icon for VLAN-interface 1.

- b. On that page that appears, select the **Enable** option next to **DHCP Relay** and select **1** for **Server Group ID**.
- c. Click **Apply**.

Figure 297 Enabling the DHCP relay agent on an interface and correlate it with a server group

DHCP Relay		DHCP Snooping	
Interface Name	Vlan-interface1		
DHCP Relay	<input checked="" type="radio"/> Enable	<input type="radio"/> Disable	
Address Match Check	<input type="radio"/> Enable	<input checked="" type="radio"/> Disable	
Server Group ID	1		
		<input type="button" value="Apply"/>	<input type="button" value="Cancel"/>

NOTE:

Because the DHCP relay agent and server are on different subnets, you need to configure a static route or dynamic routing protocol to make them reachable to each other.

Configuring DHCP snooping

DHCP snooping works between the DHCP client and server, or between the DHCP client and DHCP relay agent. It guarantees that DHCP clients obtain IP addresses from authorized DHCP servers. Also, it records IP-to-MAC bindings of DHCP clients (called DHCP snooping entries) for security purposes.

DHCP snooping does not work between the DHCP server and DHCP relay agent.

Overview

DHCP snooping defines trusted and untrusted ports to make sure clients obtain IP addresses only from authorized DHCP servers.

- **Trusted**—A trusted port can forward DHCP messages correctly to make sure the clients get IP addresses from authorized DHCP servers.
- **Untrusted**—An untrusted port discards received DHCP-ACK and DHCP-OFFER messages to prevent unauthorized servers from assigning IP addresses.

DHCP snooping reads DHCP-ACK messages received from trusted ports and DHCP-REQUEST messages to create DHCP snooping entries. A DHCP snooping entry includes the MAC and IP addresses of a client, the port that connects to the DHCP client, and the VLAN.

Application of trusted ports

Configure ports facing the DHCP server as trusted ports, and configure other ports as untrusted ports.

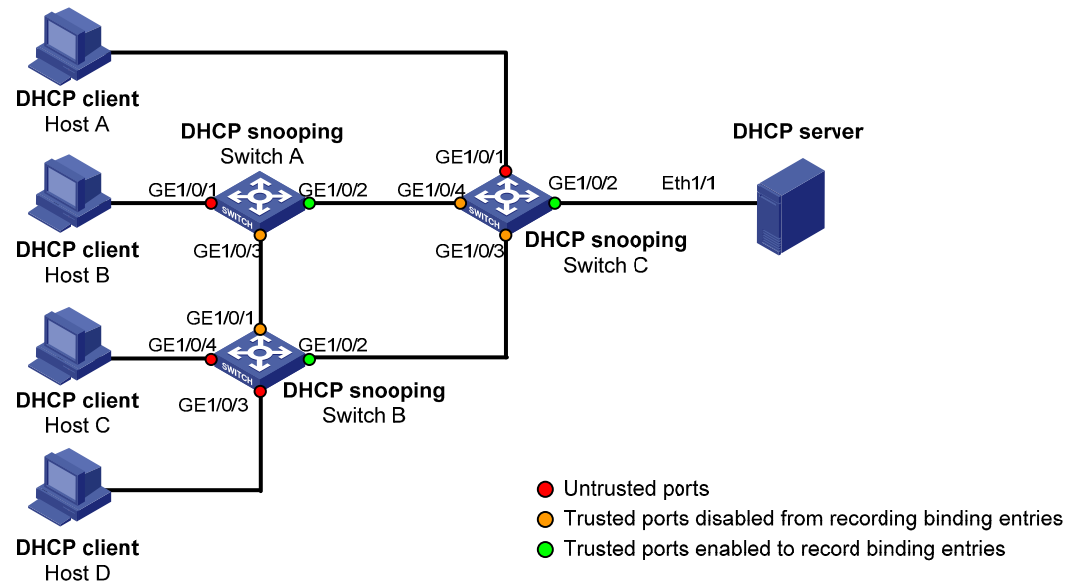

As shown in [Figure 298](#), configure the DHCP snooping device's port that is connected to the DHCP server as a trusted port. The trusted port forwards response messages from the DHCP server to the client. The untrusted port connected to the unauthorized DHCP server discards incoming DHCP response messages.

Figure 298 Configuring trusted and untrusted ports

In a cascaded network as shown in [Figure 299](#), configure each DHCP snooping device's ports connected to other DHCP snooping devices as trusted ports. To save system resources, you can disable the untrusted ports that are not directly connected to DHCP clients from generating DHCP snooping entries.

Figure 299 Trusted ports and untrusted ports in a cascaded network

[Table 98](#) describes roles of the ports shown in [Figure 299](#).

Table 98 Roles of ports

Device	Untrusted port	Trusted port disabled from recording binding entries	Trusted port enabled to record binding entries
Switch A	GigabitEthernet 1/0/1	GigabitEthernet 1/0/3	GigabitEthernet 1/0/2
Switch B	GigabitEthernet 1/0/3 and GigabitEthernet 1/0/4	GigabitEthernet 1/0/1	GigabitEthernet 1/0/2
Switch C	GigabitEthernet 1/0/1	GigabitEthernet 1/0/3 and GigabitEthernet 1/0/4	GigabitEthernet 1/0/2

DHCP snooping support for Option 82

Option 82 records the location information of the DHCP client. The administrator can locate the DHCP client to further implement security control and accounting. For more information, see "[Relay agent option \(Option 82\)](#)."

If DHCP snooping supports Option 82, it will handle a client's request according to the contents defined in Option 82, if any. The handling strategies are described in the table below.

If a reply returned by the DHCP server contains Option 82, the DHCP snooping device will remove the Option 82 before forwarding the reply to the client. If the reply contains no Option 82, the DHCP snooping device forwards it directly.

Table 99 Handling strategy of DHCP snooping support for Option 82

If a DHCP request has...	Handling strategy	The DHCP snooping device...
Option 82	Drop	Drop the message.
	Keep	Forward the message without changing Option 82.
	Replace	Forward the message after replacing the original Option 82 with the Option 82 padded in normal format.
No Option 82	N/A	Forward the message after adding the Option 82 padded in normal format.

Recommended configuration procedure

Step	Remarks
1. Enabling DHCP snooping	(Required) By default, DHCP snooping is disabled.
2. Configuring DHCP snooping functions on an interface	(Required) Specify an interface as trusted and configure DHCP snooping to support Option 82. By default, an interface is untrusted and DHCP snooping does not support Option 82. ⓘ IMPORTANT: You need to specify the ports connected to the authorized DHCP servers as trusted to make sure that DHCP clients can obtain valid IP addresses. The trusted port and the port connected to the DHCP client must be in the same VLAN.
3. Displaying DHCP snooping entries	(Optional) Display clients' IP-to-MAC bindings recorded by DHCP snooping.

Enabling DHCP snooping

1. Select **Network > DHCP** from the navigation tree.
2. Click the **DHCP Snooping** tab to enter the DHCP snooping configuration page.
3. Select the **Enable** option next to **DHCP Snooping** to enable DHCP Snooping.

DHCP snooping configuration example

Network requirements

As shown in Figure 303, a DHCP snooping device (Switch B) is connected to a DHCP server through GigabitEthernet 1/0/1, and to DHCP clients through GigabitEthernet 1/0/2 and GigabitEthernet 1/0/3.

- Enable DHCP snooping on Switch B and configure DHCP snooping to support Option 82. Configure the handling strategy for DHCP requests containing Option 82 as **replace**.
- Enable GigabitEthernet 1/0/1 to forward DHCP server responses; disable GigabitEthernet 1/0/2 and GigabitEthernet 1/0/3 from forwarding DHCP server responses.
- Configure Switch B to record clients' IP-to-MAC address bindings in DHCP-REQUEST messages and DHCP-ACK messages received from a trusted port.

Figure 303 Network diagram

Configuring Switch B

1. Enable DHCP snooping:
 - a. Select **Network > DHCP** from the navigation tree.
 - b. Click the **DHCP Snooping** tab.
 - c. Select the **Enable** option next to **DHCP Snooping** to enable DHCP snooping.

Managing services

Overview

The service management module provides six types of services: FTP, Telnet, SSH, SFTP, HTTP and HTTPS. You can enable or disable the services as needed. In this way, the performance and security of the system can be enhanced, thus secure management of the device can be achieved.

The service management module also provides the function to modify HTTP and HTTPS port numbers, and the function to associate the FTP, HTTP, or HTTPS service with an ACL, thus reducing attacks of illegal users on these services.

FTP service

The File Transfer Protocol (FTP) is an application layer protocol for sharing files between server and client over a TCP/IP network.

Telnet service

The Telnet protocol is an application layer protocol that provides remote login and virtual terminal functions on the network.

SSH service

Secure Shell (SSH) offers an approach to securely logging in to a remote device. By encryption and strong authentication, it protects devices against attacks such as IP spoofing and plain text password interception.

SFTP service

The secure file transfer protocol (SFTP) is a new feature in SSH2.0. SFTP uses the SSH connection to provide secure data transfer. The device can serve as the SFTP server, allowing a remote user to log in to the SFTP server for secure file management and transfer. The device can also serve as an SFTP client, enabling a user to login from the device to a remote device for secure file transfer.

HTTP service

The Hypertext Transfer Protocol (HTTP) is used for transferring web page information across the Internet. It is an application-layer protocol in the TCP/IP protocol suite.

You can log in to the device using the HTTP protocol with HTTP service enabled, accessing and controlling the device with Web-based network management.

HTTPS service

The Hypertext Transfer Protocol Secure (HTTPS) refers to the HTTP protocol that supports the Security Socket Layer (SSL) protocol.

The SSL protocol of HTTPS enhances the security of the device in the following ways:

- Uses the SSL protocol to ensure the legal clients to access the device securely and prohibit the illegal clients.
- Encrypts the data exchanged between the HTTPS client and the device to ensure the data security and integrity, thus realizing the security management of the device.

- Defines certificate attribute-based access control policy for the device to control the access right of the client, in order to further avoid attacks from illegal clients.

Managing services

1. Select **Network > Service** from the navigation tree.
The service management configuration page appears.

Using diagnostic tools

Ping

Use ping to determine if a specific address is reachable.

Ping operates as follows:

1. The source device sends ICMP echo requests (ECHO-REQUEST) to the destination device.
2. The destination device responds by sending ICMP echo replies (ECHO-REPLY) to the source device after receiving the ICMP echo requests.
3. The source device displays related statistics after receiving the replies.

Output of the **ping** command might include the following:

- You can ping the IP address or the host name of a destination device. A prompt appears if the target host name cannot be resolved.
- If the source device does not receive an ICMP echo reply within the timeout time, it displays:
 - A prompt.
 - Ping statistics.
- If the source device receives ICMP echo replies within the timeout time, it displays:
 - Number of bytes for each echo reply.
 - Message sequence number.
 - Time to Live (TTL).
 - Response time.
 - Ping statistics.

Ping statistics include:

- Number of echo requests sent.
- Number of echo replies received.
- Percentage of echo replies not received.
- Minimum, average, and maximum response time.

Traceroute

Traceroute retrieves the IP addresses of Layer 3 devices in the path to a specific destination. You can use traceroute to test network connectivity and identify failed nodes.

You can trace route the IP address or the host name of a destination device. If the target host name cannot be resolved, a prompt appears.

Traceroute operates as follows:

1. The source device sends a packet with a TTL value of 1 to the destination device.
2. The first hop (the device that first receives the packet) responds with a TTL-expired ICMP message to the source. In this way, the source device gets the address of the first device.

3. The source device sends a packet with a TTL value of 2 to the destination device.
4. The second hop responds with a TTL-expired ICMP message. In this way, the source device gets the address of the second device.
5. The above process continues until the packet reaches the destination device. The destination device responds with a port-unreachable ICMP message to the source. In this way, the source device gets the IP address of the destination device.

Ping operation

IPv4 ping operation

1. From the navigation tree, select **Network > Diagnostic Tools**.
The IPv4 ping configuration page appears.

Figure 309 IPv4 ping configuration page

Configuring 802.1X

Overview

802.1X is a port-based network access control protocol initially proposed by the IEEE 802 LAN/WAN committee for the security of WLANs. It has been widely used on Ethernet for access control.

802.1X controls network access by authenticating devices connected to the 802.1X-enabled LAN ports.

802.1X architecture

802.1X operates in the client/server model. It comprises three entities: the client (the supplicant), the network access device (the authenticator), and the authentication server.

Figure 317 802.1X architecture

- **Client**—A user terminal seeking access to the LAN. It must have 802.1X software to authenticate to the network access device.
- **Network access device**—Authenticates the client to control access to the LAN. In a typical 802.1X environment, the network access device uses an authentication server to perform authentication.
- **Authentication server**—Provides authentication services for the network access device. The authentication server authenticates 802.1X clients by using the data sent from the network access device, and returns the authentication results to the network access device to make access decisions. The authentication server is typically a RADIUS server. In a small LAN, you can also use the network access device as the authentication server.

Access control methods

HP implements port-based access control as defined in the 802.1X protocol, and extends the protocol to support MAC-based access control.

- **Port-based access control**—once an 802.1X user passes authentication on a port, any subsequent user can access the network through the port without authentication. When the authenticated user logs off, all other users are logged off.
- **MAC-based access control**—Each user is separately authenticated on a port. When a user logs off, no other online users are affected.

Controlled/uncontrolled port and port authorization status

802.1X defines two logical ports for the network access port: controlled port and uncontrolled port. Any packet arriving at the network access port is visible to both logical ports.

- **Controlled port**—Allows incoming and outgoing traffic to pass through when it is in the authorized state, and denies incoming and outgoing traffic when it is in the unauthorized state, as shown in Figure 318. The controlled port is set in authorized state if the client has passed authentication, and in unauthorized state, if the client has failed authentication.
- **Uncontrolled port**—Is always open to receive and transmit EAPOL frames.

Figure 318 Authorization state of a controlled port

In unauthorized state, a controlled port controls traffic in one of the following ways:

- Performs bidirectional traffic control to deny traffic to and from the client.
- Performs unidirectional traffic control to deny traffic from the client.

The device supports only unidirectional traffic control.

802.1X-related protocols

802.1X uses the Extensible Authentication Protocol (EAP) to transport authentication information for the client, the network access device, and the authentication server. EAP is an authentication framework that uses the client/server model. It supports a variety of authentication methods, including MD5-Challenge, EAP-Transport Layer Security (EAP-TLS), and Protected EAP (PEAP).

802.1X defines EAP over LAN (EAPOL) for passing EAP packets between the client and the network access device over a wired or wireless LAN. Between the network access device and the authentication server, 802.1X delivers authentication information in one of the following methods:

- Encapsulates EAP packets in RADIUS by using EAP over RADIUS (EAPOR), as described in "[EAP relay](#)."
- Extracts authentication information from the EAP packets and encapsulates the information in standard RADIUS packets, as described in "[EAP termination](#)."

Packet formats

EAP packet format

Figure 319 shows the EAP packet format.

Figure 319 EAP packet format

- **Code**—Type of the EAP packet. Options include Request (1), Response (2), Success (3), or Failure (4).
- **Identifier**—Used for matching Responses with Requests.
- **Length**—Length (in bytes) of the EAP packet. The length is the sum of the Code, Identifier, Length, and Data fields.
- **Data**—Content of the EAP packet. This field appears only in a Request or Response EAP packet. The field comprises the request type (or the response type) and the type data. Type 1 (Identify) and type 4 (MD5-challenge) are two examples for the type field.

EAPOL packet format

Figure 320 shows the EAPOL packet format.

Figure 320 EAPOL packet format

- **PAE Ethernet type**—Protocol type. It takes the value 0x888E for EAPOL.
- **Protocol version**—The EAPOL protocol version used by the EAPOL packet sender.
- **Type**—Type of the EAPOL packet. Table 103 lists the types of EAPOL packets supported by HP implementation of 802.1X.

Table 103 Types of EAPOL packets

Value	Type	Description
0x00	EAP-Packet	The client and the network access device uses EAP-Packets to transport authentication information.
0x01	EAPOL-Start	The client sends an EAPOL-Start message to initiate 802.1X authentication to the network access device.

Value	Type	Description
0x02	EAPOL-Logoff	The client sends an EAPOL-Logoff message to tell the network access device that it is logging off.

- **Length**—Data length in bytes, or length of the Packet body. If packet type is EAPOL-Start or EAPOL-Logoff, this field is set to 0, and no Packet body field follows.
- **Packet body**—Content of the packet. When the EAPOL packet type is EAP-Packet, the Packet body field contains an EAP packet.

EAP over RADIUS

RADIUS adds two attributes, EAP-Message and Message-Authenticator, for supporting EAP authentication. For the RADIUS packet format, see "[Configuring RADIUS](#)."

EAP-Message

RADIUS encapsulates EAP packets in the EAP-Message attribute, as shown in [Figure 321](#). The Type field takes 79, and the Value field can be up to 253 bytes. If an EAP packet is longer than 253 bytes, RADIUS encapsulates it in multiple EAP-Message attributes.

Figure 321 EAP-Message attribute format

Message-Authenticator

RADIUS includes the Message-Authenticator attribute in all packets that have an EAP-Message attribute to check their integrity. The packet receiver drops the packet if the calculated packet integrity checksum is different than the Message-Authenticator attribute value. The Message-Authenticator prevents EAP authentication packets from being tampered with during EAP authentication.

Figure 322 Message-Authenticator attribute format

Initiating 802.1X authentication

Both the 802.1X client and the access device can initiate 802.1X authentication.

802.1X client as the initiator

The client sends an EAPOL-Start packet to the access device to initiate 802.1X authentication. The destination MAC address of the packet is the IEEE 802.1X specified multicast address 01-80-C2-00-00-03 or the broadcast MAC address. If any intermediate device between the client and the authentication server does not support the multicast address, you must use an 802.1X client (for example, the HP iNode 802.1X client) that can send broadcast EAPOL-Start packets.

Access device as the initiator

The access device initiates authentication, if a client cannot send EAPOL-Start packets. One example is the 802.1X client available with Windows XP.

The access device supports the following modes:

- **Multicast trigger mode**—The access device multicasts Identity EAP-Request packets periodically (every 30 seconds by default) to initiate 802.1X authentication.
- **Unicast trigger mode**—Upon receiving a frame with the source MAC address not in the MAC address table, the access device sends an Identity EAP-Request packet out of the receiving port to the unknown MAC address. It retransmits the packet if no response has been received within a certain time interval.

802.1X authentication procedures

802.1X provides the following methods for authentication:

- EAP relay.
- EAP termination.

You choose either mode depending on the support of the RADIUS server for EAP packets and EAP authentication methods.

- EAP relay mode:

EAP relay is defined in IEEE 802.1X. In this mode, the network device uses EAPOR packets to send authentication information to the RADIUS server, as shown in [Figure 323](#).

In EAP relay mode, the client must use the same authentication method as the RADIUS server. On the network access device, you only need to enable EAP relay.

Figure 323 EAP relay

- EAP termination mode:

In EAP termination mode, the network access device terminates the EAP packets received from the client, encapsulates the client authentication information in standard RADIUS packets, and uses PAP or CHAP to authenticate to the RADIUS server, as shown in [Figure 324](#).

Figure 324 EAP termination

Comparing EAP relay and EAP termination

When configuring EAP relay or EAP termination, consider the following factors:

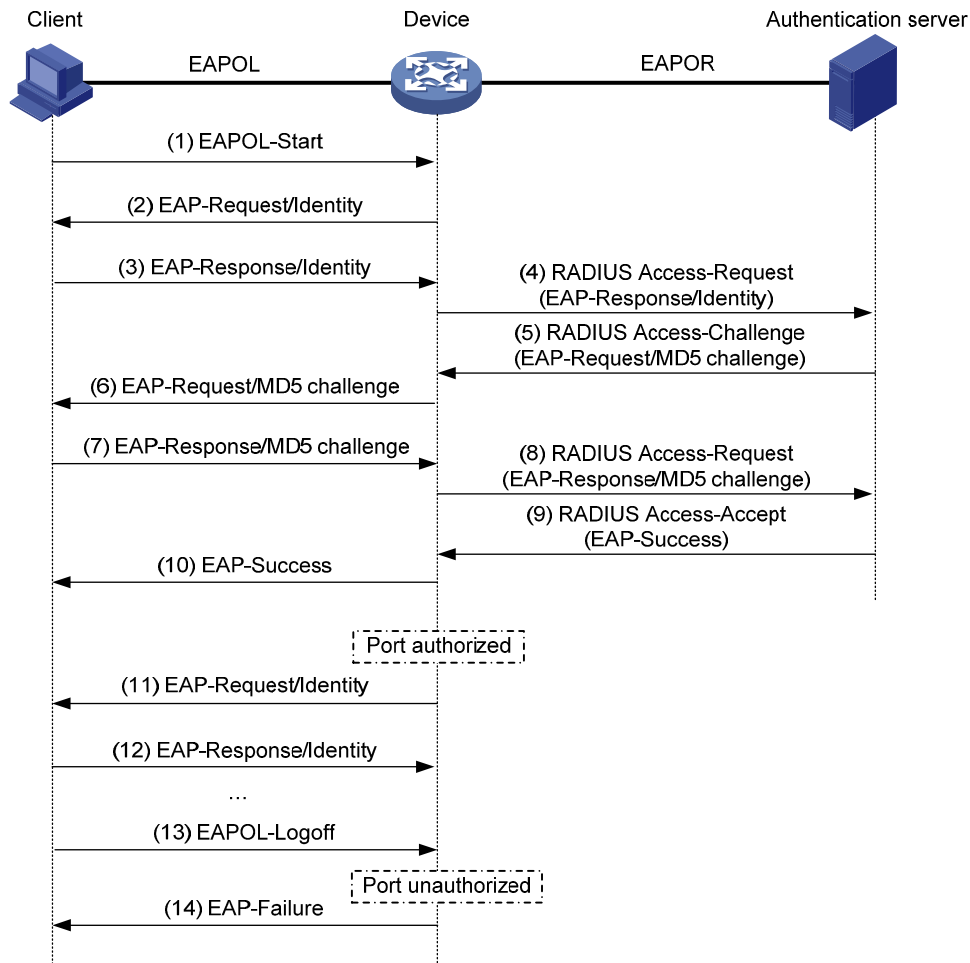

- The support of the RADIUS server for EAP packets.
- The authentication methods supported by the 802.1X client and the RADIUS server.
- If the client is using only MD5-Challenge EAP authentication or the "username + password" EAP authentication initiated by an HP iNode 802.1X client, you can use both EAP termination and EAP relay. To use EAP-TL, PEAP, or any other EAP authentication methods, you must use EAP relay.

Packet exchange method	Benefits	Limitations
EAP relay	<ul style="list-style-type: none">• Supports various EAP authentication methods.• The configuration and processing is simple on the network access device.	The RADIUS server must support the EAP-Message and Message-Authenticator attributes, and the EAP authentication method used by the client.
EAP termination	Works with any RADIUS server that supports PAP or CHAP authentication.	<ul style="list-style-type: none">• Supports only MD5-Challenge EAP authentication and the "username + password" EAP authentication initiated by an HP iNode 802.1X client.• The processing is complex on the network access device.

EAP relay

Figure 325 shows the basic 802.1X authentication procedure in EAP relay mode, assuming that EAP-MD5 is used.

Figure 325 802.1X authentication procedure in EAP relay mode

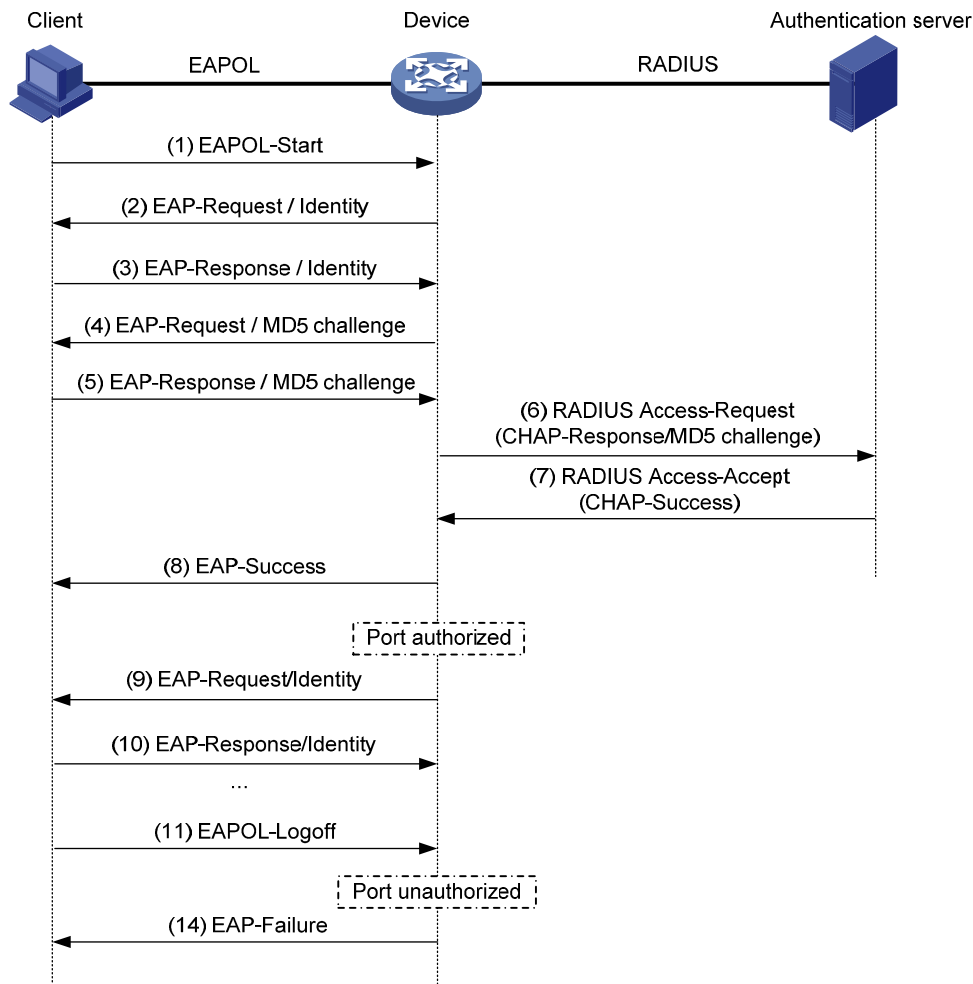

1. When a user launches the 802.1X client software and enters a registered username and password, the 802.1X client software sends an EAPOL-Start packet to the network access device.
2. The network access device responds with an Identity EAP-Request packet to ask for the client username.
3. In response to the Identity EAP-Request packet, the client sends the username in an Identity EAP-Response packet to the network access device.
4. The network access device relays the Identity EAP-Response packet in a RADIUS Access-Request packet to the authentication server.
5. The authentication server uses the identity information in the RADIUS Access-Request to search its user database. If a matching entry is found, the server uses a randomly generated challenge (EAP-Request/MD5 challenge) to encrypt the password in the entry, and sends the challenge in a RADIUS Access-Challenge packet to the network access device.
6. The network access device relays the EAP-Request/MD5 Challenge packet in a RADIUS Access-Request packet to the client.
7. The client uses the received challenge to encrypt the password, and sends the encrypted password in an EAP-Response/MD5 Challenge packet to the network access device.
8. The network access device relays the EAP-Response/MD5 Challenge packet in a RADIUS Access-Request packet to the authentication server.

9. The authentication server compares the received encrypted password with the one it generated at step 5. If the two are identical, the authentication server considers the client valid and sends a RADIUS Access-Accept packet to the network access device.
10. Upon receiving the RADIUS Access-Accept packet, the network access device sends an EAP-Success packet to the client, and sets the controlled port in the authorized state so the client can access the network.
11. After the client comes online, the network access device periodically sends handshake requests to check whether the client is still online. By default, if two consecutive handshake attempts fail, the device logs off the client.
12. Upon receiving a handshake request, the client returns a response. If the client fails to return a response after a certain number of consecutive handshake attempts (two by default), the network access device logs off the client. This handshake mechanism enables timely release of the network resources used by 802.1X users that have abnormally gone offline.
13. The client can also send an EAPOL-Logoff packet to ask the network access device for a logoff.
14. In response to the EAPOL-Logoff packet, the network access device changes the status of the controlled port from authorized to unauthorized and sends an EAP-Failure packet to the client.

EAP termination

Figure 326 shows the basic 802.1X authentication procedure in EAP termination mode, assuming that CHAP authentication is used.

Figure 326 802.1X authentication procedure in EAP termination mode

In EAP termination mode, the network access device rather than the authentication server generates an MD5 challenge for password encryption (see Step 4). The network access device then sends the MD5 challenge together with the username and encrypted password in a standard RADIUS packet to the RADIUS server.

802.1X timers

This section describes the timers used on an 802.1X device to guarantee that the client, the device, and the RADIUS server can interact with each other correctly.

- **Username request timeout timer**—Starts when the device sends an EAP-Request/Identity packet to a client in response to an authentication request. If the device receives no response before this timer expires, it retransmits the request. The timer also sets the interval at which the network device sends multicast EAP-Request/Identity packets to detect clients that cannot actively request authentication.
- **Client timeout timer**—Starts when the access device sends an EAP-Request/MD5 Challenge packet to a client. If no response is received when this timer expires, the access device retransmits the request to the client.
- **Server timeout timer**—Starts when the access device sends a RADIUS Access-Request packet to the authentication server. If no response is received when this timer expires, the access device retransmits the request to the server.

- **Handshake timer**—Sets the interval at which the access device sends client handshake requests to check the online status of a client that has passed authentication. If the device receives no response after sending the maximum number of handshake requests, it considers that the client has logged off.
- **Quiet timer**—Starts when the access device sends a RADIUS Access-Request packet to the authentication server. If no response is received when this timer expires, the access device retransmits the request to the server.
- **Periodic online user re-authentication timer**—Sets the interval at which the network device periodically re-authenticates online 802.1X users. The change to the periodic re-authentication timer applies to the users that have been online only after the old timer expires.

Using 802.1X authentication with other features

VLAN assignment

You can configure the authentication server to assign a VLAN for an 802.1X user that has passed authentication. The way that the network access device handles VLANs on an 802.1X-enabled port differs by 802.1X access control mode.

Access control	VLAN manipulation
Port-based	<p>The device assigns the VLAN to the port as the port VLAN (PVID). The authenticated 802.1X user and all subsequent 802.1X users can access the VLAN without authentication.</p> <p>When the user logs off, the previous PVID restores, and all other online users are logged off.</p>
MAC-based	<p>If the port is an access, trunk, or hybrid port, the device assigns the first authenticated user's VLAN to the port as the PVID. If a different VLAN is assigned to a subsequent user, the user cannot pass the authentication. To avoid the authentication failure of subsequent users, be sure to assign the same VLAN to all 802.1X users on these ports.</p>

NOTE:

With 802.1X authentication, a hybrid port is always assigned to a VLAN as an untagged member. After the assignment, do not reconfigure the port as a tagged member in the VLAN.

Guest VLAN

You can configure a guest VLAN on a port to accommodate users that have not performed 802.1X authentication, so they can access a limited set of network resources, such as a software server, to download anti-virus software and system patches. After a user in the guest VLAN passes 802.1X authentication, it is removed from the guest VLAN and can access authorized network resources.

The network device supports guest VLAN only on the port that performs port-based access control. The following describes the way how the network access device handles VLANs on such port

Authentication status	VLAN manipulation
No 802.1X user has performed authentication within 90 seconds after 802.1X is enabled	The device assigns the 802.1X guest VLAN to the port as the PVID. All 802.1X users on this port can access only resources in the guest VLAN. If no 802.1X guest VLAN is configured, the access device does not perform any VLAN operation.
A user in the 802.1X guest VLAN fails 802.1X authentication	If an 802.1X Auth-Fail VLAN (see " Auth-Fail VLAN ") is available, the device assigns the Auth-Fail VLAN to the port as the PVID. All users on this port can access only resources in the Auth-Fail VLAN. If no Auth-Fail VLAN is configured, the PVID on the port is still the 802.1X guest VLAN. All users on the port are in the guest VLAN.
A user in the 802.1X guest VLAN passes 802.1X authentication	<ul style="list-style-type: none"> The device assigns the VLAN specified for the user to the port as the PVID, and removes the port from the 802.1X guest VLAN. After the user logs off, the user configured PVID restores. If the authentication server assigns no VLAN, the user-configured PVID applies. The user and all subsequent 802.1X users are assigned to the user-configured port VLAN. After the user logs off, the port VLAN remains unchanged.

NOTE:

The network device assigns a hybrid port to an 802.1X guest VLAN as an untagged member.

Auth-Fail VLAN

You can configure an Auth-Fail VLAN to accommodate users that have failed 802.1X authentication because of the failure to comply with the organization security strategy, such as using a wrong password. Users in the Auth-Fail VLAN can access a limited set of network resources, such as a software server, to download anti-virus software and system patches.

The Auth-Fail VLAN does not accommodate 802.1X users that have failed authentication for authentication timeouts or network connection problems.

The network device supports Auth-Fail VLAN only on the port that performs port-based access control. The Following describes the way how the network access device handles VLANs on such port.

Authentication status	VLAN manipulation
A user fails 802.1X authentication	The device assigns the Auth-Fail VLAN to the port as the PVID. All 802.1X users on this port can access only resources in the Auth-Fail VLAN.
A user in the Auth-Fail VLAN fails 802.1X re-authentication	The Auth-Fail VLAN is still the PVID on the port, and all 802.1X users on this port are in this VLAN.
A user passes 802.1X authentication	<ul style="list-style-type: none"> The device assigns the VLAN specified for the user to the port as the PVID, and removes the port from the Auth-Fail VLAN. After the user logs off, the user-configured PVID restores. If the authentication server assigns no VLAN, the initial PVID applies. The user and all subsequent 802.1X users are assigned to the user-configured PVID. After the user logs off, the PVID remains unchanged.

NOTE:

The network device assigns a hybrid port to an 802.1X Auth-Fail VLAN as an untagged member.

ACL assignment

You can specify an ACL for an 802.1X user to control its access to network resources. After the user passes 802.1X authentication, the authentication server, either the local access device or a RADIUS server, assigns the ACL to the port to filter the traffic from this user. In either case, you must configure the ACL on the access device. You can change ACL rules while the user is online.

Configuration prerequisites

When you configure 802.1X, follow these restrictions and guidelines:

- Configure an ISP domain and AAA scheme (local or RADIUS authentication) for 802.1X users. For more information, see "[Configuring AAA](#)" and "[Configuring RADIUS](#)."
- If RADIUS authentication is used, create user accounts on the RADIUS server.
- If local authentication is used, create local user accounts on the access device and specify the LAN access service for the user accounts. For more information, see "[Configuring users and user groups](#)."

Recommended configuration procedure

Step	Remarks
1. Configuring 802.1X globally	Required. Enable 802.1X authentication globally and configure the authentication method and advanced parameters. By default, 802.1X authentication is disabled globally.
2. Configuring 802.1X on a port	Required. Enable 802.1X authentication on the specified port and configure 802.1X parameters for the port. By default, 802.1X authentication is disabled on a port.

Configuring 802.1X globally

1. From the navigation tree, select **Authentication > 802.1X**.

Figure 327 802.1X global configuration

802.1X

802.1X Configuration

☐ Enable 802.1X

Add
Del Selected

2. In the **802.1X Configuration** area, select the **Enable 802.1X** box.
3. Select an authentication method from the **Authentication Method** list.

Authentication Method list

- **CHAP**—Sets the access device to perform EAP termination and use CHAP to communicate with the RADIUS server.
- **PAP**—Sets the access device to perform EAP termination and use PAP to communicate with the RADIUS server.
- **EAP**—Sets the access device to relay EAP packets, and supports any of the EAP authentication methods to communicate with the RADIUS server.

For more information about EAP relay and EAP termination, see "[Comparing EAP relay and EAP termination](#)."

4. Click **Advanced**.

The advanced 802.1X configuration area is expanded, as shown in [Figure 328](#).

Figure 328 802.1X configuration page

▼ Advanced

Quiet	<input type="checkbox"/> Enable the Quiet Function	Quiet Period	60 seconds (10-120, Default = 60)
Retry Times	2 (1-10, Default = 2)	TX-Period	30 seconds (10-120, Default = 30)
Handshake Period	15 seconds (5-1024, Default = 15)	Re-Authentication Period	3600 seconds (60-7200, Default = 3600)
Supplicant Timeout Time	30 seconds (1-120, Default = 30)	Server Timeout Time	100 seconds (100-300, Default = 100)

5. Configure advanced 802.1X settings as described in [Table 104](#). For more information about 802.1X timers, see "[802.1X timers](#)."
6. Click **Apply**.

Table 104 Configuration items

Item	Description
Quiet	Specify whether to enable the quiet timer. The quiet timer enables the network access device to wait a period of time defined by the Quiet Period option before it can process any authentication request from a client that has failed an 802.1X authentication.
Quiet Period	Set the value of the quiet timer.
Retry Times	Set the maximum number of authentication request attempts. The network access device retransmits an authentication request if it does not receive a response to the request it has sent to the client within a period of time (specified by using the TX Period option or the Supplicant Timeout Time option). The network access device stops retransmitting the request, if it has made the maximum number of request transmission attempts but still received no response.
TX-Period	Set the username request timeout timer.
Handshake Period	Set the handshake timer. For information about how to enable the online user handshake function, see "Configuring 802.1X on a port."
Re-Authentication Period	Set the periodic online user re-authentication timer. For information about how to enable periodic online user re-authentication on a port, see "Configuring 802.1X on a port."
Supplicant Timeout Time	Set the client timeout timer.
Server Timeout Time	Set the server timeout timer.

NOTE:

You can set the client timeout timer to a high value in a low-performance network, and adjust the server timeout timer to adapt to the performance of different authentication servers. In most cases, the default settings are sufficient.

Configuring 802.1X on a port

Configuration guidelines

When you configure 802.1X on a port, follow these restrictions and guidelines:

- 802.1X configuration on a specific port can take effect only after global 802.1X and port-specific 802.1X are enabled.
- If the PVID of a port is a voice VLAN, the 802.1X function cannot take effect on the port.
- 802.1X is mutually exclusive with link aggregation and service loopback group configuration on a port.

Configuration procedure

1. From the navigation tree, select **Authentication > 802.1X**.

The **Ports With 802.1X Enabled** area displays the port-specific 802.1X configuration.

2. In the **Ports With 802.1X Enabled** area, click **Add**.
3. Configure 802.1X features on a port as shown in [Figure 329](#), and then click **Apply**.

Figure 329 Configuring 802.1X on a port

Apply

Cancel

[Table 105](#) describes the configuration items.

Table 105 Configuration items

Item	Description
Port	Select a port where you want to enable 802.1X. Only 802.1X-disabled ports are available.
Port Control	Select an access control method for the port, MAC Based or Port Based .
Port Authorization	Select the 802.1X authorization mode for the port: <ul style="list-style-type: none"> • Auto—Places the specified or all ports initially in the unauthorized state to allow only EAPOL packets to pass, and after a user passes authentication, sets the port in the authorized state to allow access to the network. You can use this option in most scenarios. • Force-Authorized—Places the specified or all ports in the authorized state, enabling users on the ports to access the network without authentication. • Force-Unauthorized—Places the specified or all ports in the unauthorized state, denying any access requests from users on the ports.
Max Number of Users	Set the maximum number of concurrent 802.1X users on the port.
Enable Handshake	Select the box to enable the online user handshake function. The online user handshake function checks the connectivity status of online 802.1X users. The network access device sends handshake messages to online users at the interval specified by the Handshake Period option. If no response is received from an online user after the maximum number of handshake attempts (set by the Retry Times option) has been made, the network access device sets the user in the offline state. For information about the timers, see Table 104 .

Item	Description
Enable Re-Authentication	Select the box to enable periodic online user re-authentication on the port. Periodic online user re-authentication tracks the connection status of online users and updates the authorization attributes assigned by the server, such as the ACL, and VLAN. The re-authentication interval is specified by the Re-Authentication Period option in Table 104 .
Guest VLAN	Specify an existing VLAN as the guest VLAN. For more information, see " Configuring an 802.1X guest VLAN ."
Auth-Fail VLAN	Specify an existing VLAN as the Auth-Fail VLAN to accommodate users that have failed 802.1X authentication. For more information, see " Configuring an Auth-Fail VLAN ."

Configuring an 802.1X guest VLAN

Configuration prerequisites

- Create the VLAN to be specified as the 802.1X guest VLAN.
- On the 802.1X-enabled port that performs port-based access control, enable 802.1X multicast trigger at the CLI. (802.1X multicast trigger is enabled by default.)

Configuration guidelines

When you configure an 802.1X guest VLAN, follow these restrictions and guidelines:

- You can configure only one 802.1X guest VLAN on a port. The 802.1X guest VLANs on different ports can be different.
- Assign different IDs to the voice VLAN, the PVID, and the 802.1X guest VLAN on a port, so the port can correctly process incoming VLAN tagged traffic.
- With 802.1X authentication, a hybrid port is always assigned to a VLAN as an untagged member. After the assignment, do not re-configure the port as a tagged member in the VLAN.

Configuring an Auth-Fail VLAN

Configuration prerequisites

- Create the VLAN to be specified as the 802.1X Auth-Fail VLAN.
- On the 802.1X-enabled port that performs port-based access control, enable 802.1X multicast trigger. (802.1X multicast trigger is enabled by default.)

Configuration guidelines

Assign different IDs to the voice VLAN, PVID and the 802.1X Auth-Fail VLAN on a port, so the port can correctly process VLAN tagged incoming traffic.

Configuration examples

MAC-based 802.1X configuration example

Network requirements

As shown in [Figure 330](#), the access device performs 802.1X authentication for users that connect to port GigabitEthernet 1/0/1. Implement MAC-based access control on the port, so the logoff of one user does not affect other online 802.1X users. Enable periodic re-authentication of online users on the port, so that the server can periodically update the authorization information of the users.

Use RADIUS servers to perform authentication, authorization, and accounting for the 802.1X users. If RADIUS accounting fails, the access device logs the user off. The RADIUS servers run CAMS or IMC.

Configure the host at 10.1.1.1 as the primary authentication and secondary accounting servers, and the host at 10.1.1.2 as the secondary authentication and primary accounting servers. Assign all users to the ISP domain **test**.

Configure the shared key as **name** for packets between the access device and the authentication server, and the shared key as **money** for packets between the access device and the accounting server.

Exclude the ISP domain name from the username sent to the RADIUS servers.

Specify the device to try up to 5 times at an interval of 5 seconds in transmitting a packet to the RADIUS server until it receives a response from the server, and to send real time accounting packets to the accounting server every 15 minutes.

Figure 330 Network diagram

Configuring IP addresses

Assign an IP address to each interface as shown in [Figure 330](#). Make sure the supplicant, switch, and servers can reach each other. (Details not shown.)

Configuring the RADIUS server

For more information about the RADIUS configuration, see "[Configuring RADIUS](#)."

Configuring 802.1X on the switch

1. Configure 802.1X globally:
 - a. From the navigation tree, select **Authentication > 802.1X**.
 - b. Select the **Enable 802.1X** box, select the authentication method as **CHAP**, and click **Apply**.

```

Configuring AAA

Overview

Authentication, Authorization, and Accounting (AAA) provides a uniform framework for implementing network access management. It provides the following security functions:

- **Authentication**—Identifies users and determines whether a user is valid.
- **Authorization**—Grants different users different rights and controls their access to resources and services. For example, a user who has successfully logged in to the switch can be granted read and print permissions to the files on the switch.
- **Accounting**—Records all network service usage information of users, including the service type, start time, and traffic. The accounting function not only provides the information required for charging, but also allows for network security surveillance.

AAA can be implemented through multiple protocols. The switch series supports RADIUS, the most commonly used protocol in practice. For more information about RADIUS, see "[Configuring RADIUS](#)."

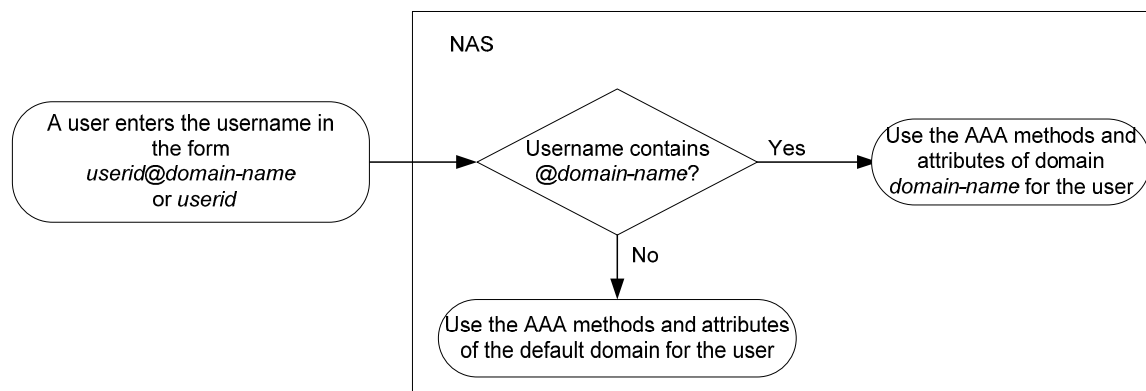

AAA usually uses a client/server model. The client runs on the network access server (NAS) and the server maintains user information centrally. In an AAA network, a NAS is a server for users but a client for the AAA servers, as shown in [Figure 354](#).

Figure 354 Network diagram for AAA

The NAS manages users based on Internet service provider (ISP) domains. On the NAS, each user belongs to one ISP domain. The NAS determines the ISP domain for a user by the username entered by the user at login, as shown in [Figure 355](#).

Figure 355 Determining the ISP domain of a user by the username

The authentication, authorization, and accounting of a user depends on the AAA methods configured for the domain that the user belongs to. If no specific AAA methods are configured for the domain, the default methods are used. By default, a domain uses local authentication, local authorization, and local accounting.

AAA allows you to manage users based on their access types:

- **LAN-access users**—Users on a LAN who must pass, for example, 802.1X or MAC address authentication to access the network.
- **Login users**—Users who want to log in to the switch, including SSH users, Telnet users, web users, FTP users, and terminal users.

In addition, AAA provides command authorization for login users to enhance security. With this function configured, the NAS has every single command entered by a login user verified by the authorization server to restrict the user to execute only authorized commands.

Recommended AAA configuration procedure

Before configuring AAA, complete the following tasks:

- To implement local authentication, configure local users on the access device as described in "Configuring users and user groups."
- To implement RADIUS authentication, create the RADIUS schemes to be used as described in "Configuring RADIUS."

Step	Remarks
1. Configuring an ISP domain	(Optional.) Create ISP domains and specify one of them as the default ISP domain. By default, there is an ISP domain named system , which is the default ISP domain.
2. Configuring authentication methods for the ISP domain	(Optional.) Configure authentication methods for various types of users. By default, all types of users use local authentication.

Step	Remarks
3. Configuring authorization methods for the ISP domain	(Optional.) Specify the authorization methods for various types of users. By default, all types of users use local authorization.
4. Configuring accounting methods for the ISP domain	(Optional.) Specify the accounting methods for various types of users. By default, all types of users use local accounting.

Configuring an ISP domain

1. Select **Authentication** > **AAA** from the navigation tree.
The **Domain Setup** page appears.

Configuring portal authentication

Overview

Portal authentication helps control access to the Internet. It is also called "Web authentication." A website implementing portal authentication is called a "portal website."

With portal authentication, an access device redirects all users to the portal authentication page. All users can access the free services provided on the portal website. To access the Internet, however, a user must pass portal authentication.

A user can access a known portal website and enter a username and password for authentication. This authentication mode is called active authentication. There is another authentication mode, forced authentication, in which the access device forces a user who is trying to access the Internet through HTTP to log on to a portal website for authentication.

The portal feature provides the flexibility for Internet service providers (ISPs) to manage services. A portal website can, for example, present advertisements and deliver community and personalized services. In this way, broadband network providers, equipment vendors, and content service providers form an industrial ecological system.

Extended portal functions

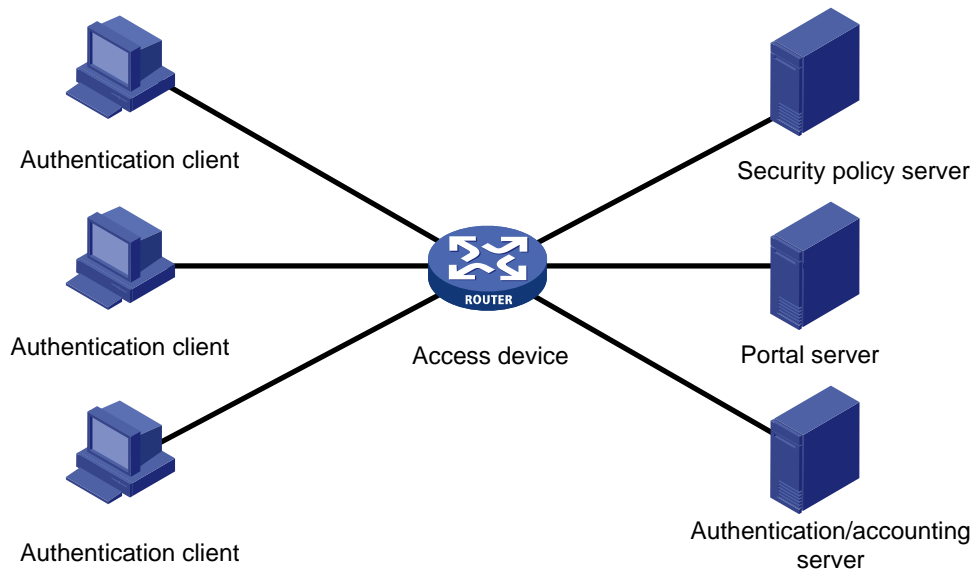

By forcing patching and anti-virus policies, extended portal functions help users to defend against viruses. Portal authentication supports the following extended functions:

- **Security check**—Works after identity authentication succeeds to check whether the required anti-virus software, virus definition file, and operating system (OS) patches are installed, and whether there is any unauthorized software installed on the user host.
- **Resource access restriction**—Allows a user passing identity authentication to access only network resources in the quarantined area, such as the anti-virus server and the patch server. Only users passing both identity authentication and security check can access restricted network resources.

Portal system components

A typical portal system comprises these basic components: authentication client, access device, portal server, authentication/accounting server, and security policy server.

Figure 367 Portal system components

Authentication client

An authentication client is an entity seeking access to network resources. It is typically an end-user terminal, such as a PC. The client can use a browser or a portal client software for portal authentication. Client security check is implemented through communications between the client and the security policy server.

Access device

An access device controls user access. It can be a switch or a router that provides the following functions:

- Redirecting all HTTP requests from unauthenticated users in authentication subnets to the portal server.
- Interacting with the portal server, the security policy server, and the authentication/accounting server for identity authentication, security check, and accounting.
- Allowing users who have passed identity authentication and security check to access granted Internet resources.

Portal server

A portal server listens to authentication requests from authentication clients and exchanges client authentication information with the access device. It provides free portal services and pushes Web authentication pages to users.

A portal server can be an entity independent of the access device or an entity embedded in the access device. In this document, the term "portal server" refers to an independent portal server, and the term "local portal server" refers to an embedded portal server.

Authentication/accounting server

An authentication/accounting server implements user authentication and accounting through interaction with the access device.

Only a RADIUS server can serve as the remote authentication/accounting server in a portal system.

Security policy server

A security policy server interacts with authentication clients and access devices for security check and resource authorization.

The components of a portal system interact in the following procedure:

1. When an unauthenticated user enters a website address in the address bar of the browser to access the Internet, an HTTP request is created and sent to the access device, which redirects the HTTP request to the Web authentication homepage of the portal server. For extended portal functions, authentication clients must run the portal client software.
2. On the authentication homepage/authentication dialog box, the user enters and submits the authentication information, which the portal server then transfers to the access device.
3. Upon receipt of the authentication information, the access device communicates with the authentication/accounting server for authentication and accounting.
4. After successful authentication, the access device checks whether there is a corresponding security policy for the user. If not, it allows the user to access the Internet. Otherwise, the client communicates with the access device and the security policy server for security check. If the client passes security check, the security policy server authorizes the user to access the Internet resources.

NOTE:

To implement security check, use the HP iNode client.

Portal authentication supports NAT traversal whether it is initiated by a Web client or an HP iNode client. When the portal authentication client is on a private network, but the portal server is on a public network and the access device is enabled with NAT, network address translations performed on the access device do not affect portal authentication.

Portal system using the local portal server

System components

In addition to use a separate device as the portal server, a portal system can also use the local portal server function of the access device to authenticate Web users directly. A portal system using the local portal server does not support extended portal functions. No security policy server is needed for local portal service. In this case, the portal system consists of only three components: authentication client, access device, and authentication/accounting server.

Figure 368 Portal system using the local portal server

NOTE:

The local portal server function of the access device only implements some simple portal server functions, allowing users to log in and log out through the Web interface. It cannot take the place of an independent portal server.

Protocols used for interaction between the client and local portal server

HTTP and HTTPS can be used for communication between an authentication client and an access device providing the local portal server function. If HTTP is used, there are potential security problems because HTTP packets are transferred in plain text. If HTTPS is used, secure data transmission is ensured because HTTPS packets are transferred in cipher text based on SSL.

Portal authentication modes

Portal authentication may work at Layer 2 or Layer 3 of the OSI model.

Layer 2 portal authentication

You can enable Layer 2 portal authentication on an access device's Layer 2 ports that connect authentication clients, so that only clients whose MAC addresses pass authentication can access the external network. Only the local portal server provided by the access device supports Layer 2 portal authentication.

Layer 2 portal authentication allows the authentication server to assign different VLANs according to user authentication results so that access devices can thereby control user access to resources. After a client passes authentication, the authentication server can assign an authorized VLAN to allow the user to access the resources in the VLAN. If a client fails authentication, the authentication server can assign an Auth-Fail VLAN. Layer 3 portal authentication does not support VLAN assignment.

Layer 3 portal authentication

In Layer 3 authentication mode, portal authentication is enabled on an access device's Layer 3 interfaces that connect authentication clients. Portal authentication performed on a Layer 3 interface can be direct authentication or cross-subnet authentication. In direct authentication, no Layer 3 forwarding devices exist between the authentication client and the access device. In cross-subnet authentication, Layer 3 forwarding devices may exist between the authentication client and the access device.

- Direct authentication
Before authentication, a user manually configures a public IP address or directly obtains a public IP address through DHCP, and can access only the portal server and predefined free websites. After passing authentication, the user can access the network resources.
- Cross-subnet authentication
Cross-subnet authentication is similar to direct authentication, but it allows Layer 3 forwarding devices to be present between the authentication client and the access device.
In direct authentication and cross-subnet authentication, the IP address of a client is used for identification of the client. After a client passes authentication, the access device generates an access control list (ACL) for the client based on the client's IP address to permit packets from the client to go through the access port. Because no Layer 3 devices are present between the authentication clients and the access device in direct authentication, the access device can directly learn the MAC addresses of the clients, and thus can control the forwarding of packets from clients in a more granular way by also using the learnt MAC addresses.

Portal support for EAP

Authentication by using the username and password is less secure. Digital certificate authentication is usually used to ensure higher security.

The Extensible Authentication Protocol (EAP) supports several digital certificate-based authentication methods, for example, EAP-TLS. Working together with EAP, portal authentication can implement digital certificate-based user authentication.

Figure 369 Portal support for EAP working flow diagram

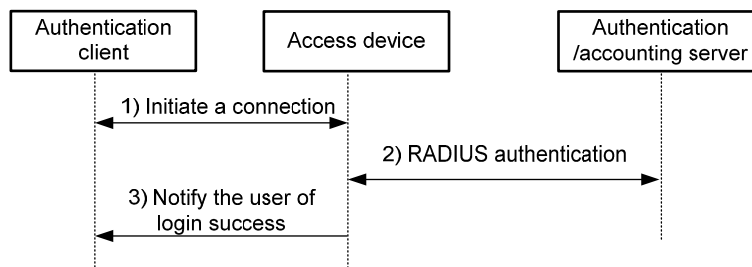

As shown in Figure 369, the authentication client and the portal server exchange EAP authentication packets. The portal server and the access device exchange portal authentication packets that carry the EAP-Message attributes. The access device and the RADIUS server exchange RADIUS packets that carry the EAP-Message attributes. The RADIUS server that supports the EAP server function processes the EAP packets encapsulated in the EAP-Message attributes, and provides the EAP authentication result. During the whole EAP authentication process, the access device does not process the packets that carry the EAP-Message attributes but only transports them between the portal server and the RADIUS server. Therefore, no additional configuration is needed on the access device.

NOTE:

- This function requires the cooperation of the HP IMC portal server and HP iNode portal client.
- Only Layer 3 portal authentication that uses a remote portal server supports EAP authentication.

Layer 2 portal authentication process

Figure 370 Local Layer-2 portal authentication process

The process of local Layer-2 portal authentication is as follows:

1. The portal authentication client sends an HTTP or HTTPS request. Upon receiving the HTTP request, the access device redirects it to the listening IP address of the local portal server, which then pushes a Web authentication page to the authentication client. The user types the username and password on the Web authentication page. The listening IP address of the local portal server is the IP address of a Layer 3 interface on the access device that can communicate with the portal client. Usually, it is a loopback interface's IP address.
2. The access device and the RADIUS server exchange RADIUS packets to authenticate the user.
3. If the user passes RADIUS authentication, the local portal server pushes a logon success page to the authentication client.

Assignment of authorized ACLs

The device can use ACLs to control user access to network resources and limit user access rights. With authorized ACLs specified on the authentication server, when a user passes authentication, the authentication server assigns an authorized ACL for the user, and the device filters traffic from the user on

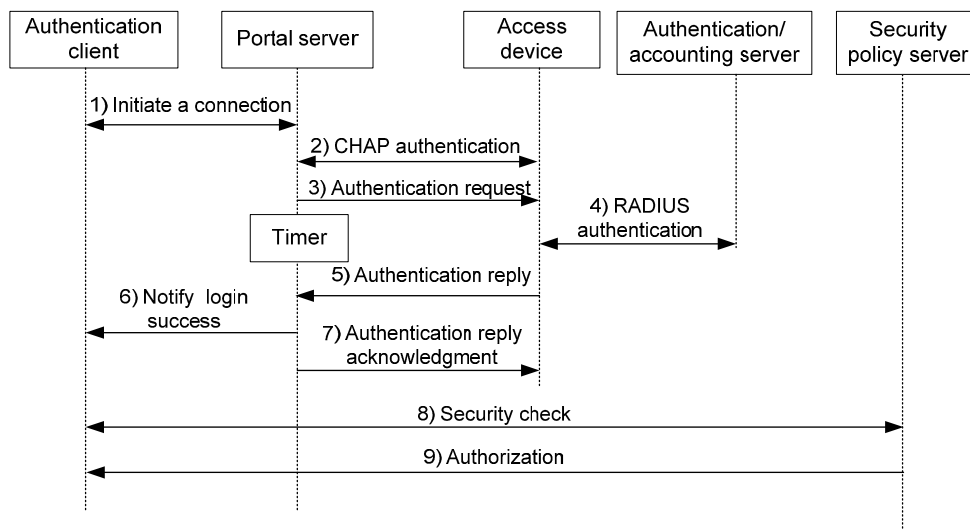

the access port according to the authorized ACL. You must configure the authorized ACLs on the access device if you specify authorized ACLs on the authentication server. To change the access right of a user, you can specify a different authorized ACL on the authentication server or change the rules of the corresponding authorized ACL on the device.

Layer 3 portal authentication process

Direct authentication and cross-subnet authentication share the same authentication process.

Direct authentication/cross-subnet authentication process (with CHAP/PAP authentication)

Figure 371 Direct authentication/cross-subnet authentication process

The direct authentication/cross-subnet authentication process is as follows:

1. A portal user initiates an authentication request through HTTP. When the HTTP packet arrives at the access device, the access device allows it to pass if it is destined for the portal server or a predefined free website, or redirects it to the portal server if it is destined for other websites. The portal server provides a Web page for the user to enter the username and password.
2. The portal server and the access device exchange Challenge Handshake Authentication Protocol (CHAP) messages. For Password Authentication Protocol (PAP) authentication, this step is skipped.
3. The portal server assembles the username and password into an authentication request message and sends it to the access device. Meanwhile, the portal server starts a timer to wait for an authentication acknowledgment message.
4. The access device and the RADIUS server exchange RADIUS packets to authenticate the user.
5. The access device sends an authentication reply to the portal server.
6. The portal server sends an authentication success message to the authentication client to notify it of logon success.
7. The portal server sends an authentication reply acknowledgment to the access device.

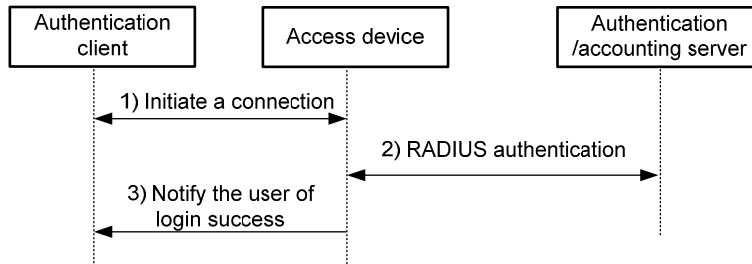

With extended portal functions, the process includes additional steps:

8. The security policy server exchanges security check information with the authentication client to check whether the authentication client meets the security requirements.

9. Based on the security check result, the security policy server authorizes the user to access certain resources, and sends the authorization information to the access device. The access device then controls access of the user based on the authorization information.

Authentication process with the local portal server

Figure 372 Authentication process with local portal server

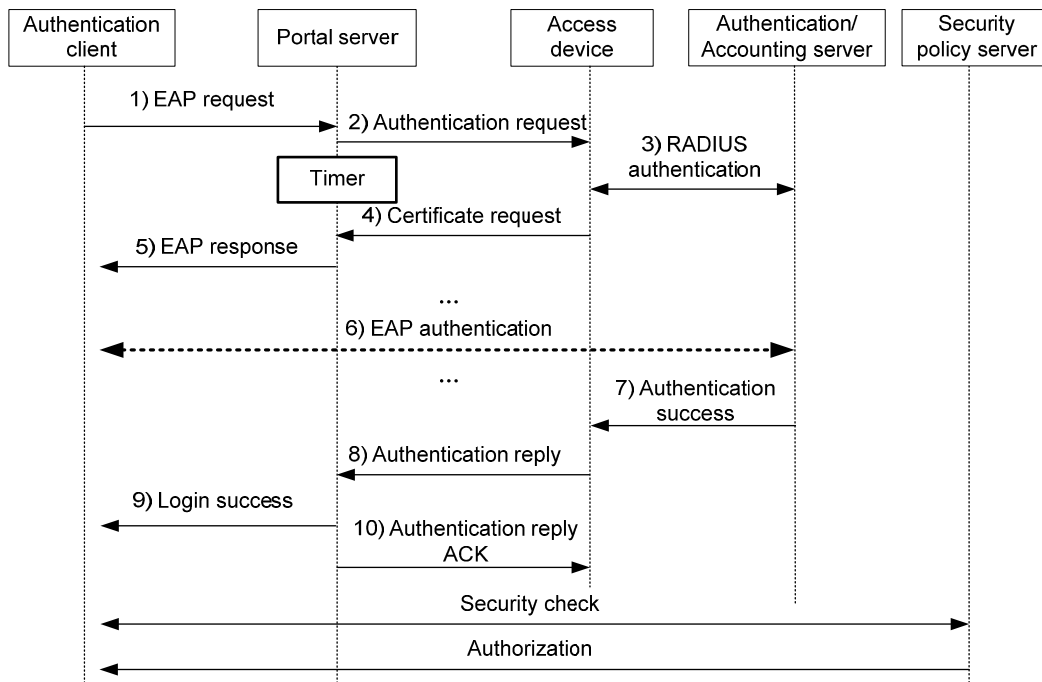

With local portal server, the direct/cross-subnet authentication process is as follows:

1. A portal client initiates authentication by sending an HTTP or HTTPS request. When the HTTP packet arrives at an access device using the local portal server, it is redirected to the local portal server, which then pushes a Web authentication page for the user to enter the username and password. The listening IP address of the local portal server is the IP address of a Layer 3 interface on the access device that can communicate with the portal authentication client.
2. The access device and the RADIUS server exchange RADIUS packets to authenticate the user.
3. If the user passes authentication, the local portal server pushes a logon success page to the authentication client, informing the user of the authentication (login) success.

Portal support for EAP authentication process

Figure 373 Portal support for EAP authentication process

All portal authentication modes share the same EAP authentication steps. The following takes the direct portal authentication as an example to show the EAP authentication process:

1. The authentication client sends an EAP Request/Identity message to the portal server to initiate an EAP authentication process.
2. The portal server sends a portal authentication request to the access device, and starts a timer to wait for the portal authentication reply. The portal authentication request contains several EAP-Message attributes, which are used to encapsulate the EAP packet sent from the authentication client and carry the certificate information of the client.
3. After the access device receives the portal authentication request, it constructs a RADIUS authentication request and sends it to the RADIUS server. The EAP-Message attributes in the RADIUS authentication request are those carried in the received portal authentication request.
4. The access device sends a certificate request to the portal server according to the reply received from the RADIUS server. The certificate request also contains several EAP-Message attributes, which are used to transfer the certificate information of the RADIUS server. The EAP-Message attributes in the certificate request are those carried in the RADIUS authentication reply.
5. After receiving the certificate request, the portal server sends an EAP authentication reply to the authentication client, carrying the EAP-Message attribute values.
6. The authentication client sends another EAP request to continue the EAP authentication with the RADIUS server, during which there may be several portal authentication requests. The subsequent authentication processes are the same as that initiated by the first EAP request, except that the EAP request types vary with the EAP authentication phases.
7. After the authentication client passes the EAP authentication, the RADIUS server sends an authentication reply to the access device. This reply carries the EAP-Success message in the EAP-Message attribute.
8. The access device sends an authentication reply to the portal server. This reply carries the EAP-Success message in the EAP-Message attribute.
9. The portal server notifies the authentication client of the authentication success.
10. The portal server sends an authentication replay acknowledgment to the access device.

The remaining steps are for extended portal authentication. For more information about the steps, see the portal authentication process with CHAP/PAP authentication.

Configuring portal authentication

Configuration prerequisites

The portal feature provides a solution for user identity authentication and security check. However, the portal feature cannot implement this solution by itself. RADIUS authentication needs to be configured on the access device to cooperate with the portal feature to complete user authentication.

The prerequisites for portal authentication configuration are as follows:

- The portal-enabled interfaces of the access device are configured with valid IP addresses or have obtained valid IP addresses through DHCP.
- The portal server and the RADIUS server have been installed and configured correctly. Local portal authentication requires no independent portal server.
- The portal client, access device, and servers can reach each other.
- With RADIUS authentication, usernames and passwords of the users are configured on the RADIUS server, and the RADIUS client configuration is performed on the access device. For information about RADIUS client configuration, see "[Configuring RADIUS](#)."

- To implement extended portal functions, install and configure IMC EAD, and make sure the ACLs configured on the access device correspond to those specified for the resources in the quarantined area and for the restricted resources on the security policy server. On the access device, the security policy server address is the same as the authentication server address. For more information about security policy server configuration on the access device, see "[Configuring RADIUS](#)."

Recommended configuration procedure for Layer 2 portal authentication

Step	Remarks
1. Configuring the Layer 2 portal service	<p>Required.</p> <p>Configure a local portal server, apply the portal server to a Layer 2 interface, and configure the Layer 2 portal authentication parameters.</p> <p>By default, no local portal server is configured.</p> <p> IMPORTANT:</p> <p>To ensure normal operation of portal authentication on a Layer 2 interface, do not configure port security or guest VLAN of 802.1X on the interface.</p>
2. Configuring advanced parameters for portal authentication	<p>Optional.</p> <p>Configure Web proxy server ports, an auto redirection URL, the time that the device must wait before redirecting an authenticated user to the auto redirection URL, and the portal user moving function.</p>
3. Configuring a portal-free rule	<p>Optional.</p> <p>Configure a portal-free rule, specifying the source and destination information for packet filtering</p> <p>A portal-free rule allows specified users to access specified external websites without portal authentication. Packets matching a portal-free rule do not trigger portal authentication and the users can directly access the specified external websites.</p> <p>By default, no portal-free policy is configured.</p>

Recommended configuration procedure for Layer 3 portal authentication

Step	Remarks
1. Configuring the Layer 3 portal service	<p>Required.</p> <p>Configure a portal server, apply the portal server to a Layer 3 interface, and configure the portal authentication parameters.</p> <p>By default, no portal server is configured.</p>
2. Configuring advanced parameters for portal authentication	<p>Optional.</p> <p>Configure an auto redirection URL, the time that the device must wait before redirecting an authenticated user to the auto redirection URL, and the portal user moving function.</p>

Step	Remarks
3. Configuring a portal-free rule	<p>Optional.</p> <p>Configure a portal-free rule, specifying the source and destination information for packet filtering</p> <p>A portal-free rule allows specified users to access specified external websites without portal authentication. Packets matching a portal-free rule will not trigger portal authentication and the users can directly access the specified external websites.</p> <p>By default, no portal-free policy is configured.</p>

Configuring the Layer 2 portal service

1. Select **Authentication > Portal** from the navigation tree.
The portal server configuration page appears.

☐ Enable Support for Portal User Moving

3. Configure the advanced parameters as described in [Table 114](#).
4. Click **Apply**.

Table 114 Configuration items

Item	Description
Web Proxy Server Ports	<p>Configure the Web proxy server ports to allow HTTP requests proxied by the specified proxy servers to trigger portal authentication. By default, only HTTP requests that are not proxied can trigger portal authentication.</p> <p>To make sure a user using a Web proxy server can trigger portal authentication, you need to add the port number of the proxy server on the device and the user needs to specify the listening IP address of the local portal server as a proxy exception in the browser. Thus, HTTP packets that the portal user sends to the local portal server are not sent to the proxy server.</p> <p> IMPORTANT:</p> <ul style="list-style-type: none"> • Only Layer 2 portal authentication supports this feature. • If a user's browser uses the Web Proxy Auto-Discovery (WPAD) protocol to discover Web proxy servers, add the port numbers of the Web proxy servers on the device, and configure portal-free rules to allow user packets destined for the IP address of the WPAD server to pass without authentication.
Redirection URL	<p>Specify the auto redirection URL to which users will be automatically redirected after they pass portal authentication.</p> <p>To access the network, an unauthenticated user either goes to or is automatically forced to the portal authentication page for authentication. If the user passes portal authentication and the access device is configured with an auto redirection URL, the access device redirects the user to the URL after a specific period of time.</p>
Wait-Time	<p>Set the time that the device must wait before redirecting an authenticated portal user to the auto redirection URL.</p>
Enable Support for Portal User Moving	<p>Specify whether to enable support for portal user moving.</p> <p>In scenarios where there are hubs, Layer 2 switches, or APs between users and the access devices, if an authenticated user moves from an access port to another Layer 2-portal-authentication-enabled port of the device without logging off, the user cannot get online when the original port is still up. The reason is that the original port is still maintaining the authentication information of the user and the device does not permit such a user to get online from another port by default.</p> <p>To solve the problem described above, enable support for portal user moving on the device. Then, when a user moves from a port of the device to another, the device provides services in either of the following two ways:</p> <ul style="list-style-type: none"> • If the original port is still up and the two ports belong to the same VLAN, the device allows the user to continue to access the network without re-authentication, and uses the new port information for accounting of the user. • If the original port is down or the two ports belong to different VLANs, the device removes the authentication information of the user from the original port and authenticates the user on the new port. <p> IMPORTANT:</p> <p>For a user with authorization information (such as authorized VLAN) configured, after the user moves from a port to another, the device tries to assign the authorization information to the new port. If the operation fails, the device deletes the user's information from the original port and re-authenticates the user on the new port.</p>

Configuring a portal-free rule

1. Select **Authentication** > **Portal** from the navigation tree
2. Click the **Free Rule** tab to enter the portal-free rule list page.

Figure 380 Portal-free rule list

Number	Description	Operation
0	source IP 1.1.11.0(255.255.255.0);	

Add

3. Click **Add**.
The page for adding a new portal-free rule appears.

Portal authentication configuration examples

Configuring Layer 2 portal authentication

Network requirements

As shown in [Figure 382](#), a host is directly connected to a switch. The switch performs Layer 2 portal authentication for users connected to port GigabitEthernet 1/0/1. Configure the switch to perform the following functions:

- Uses IMC as the remote RADIUS server for authentication, authorization, and accounting.
- Uses the remote DHCP server to assign IP addresses to users.
- Uses 4.4.4.4 as the listening IP address of the local portal server and transmits authentication data through HTTP.
- Allows users to access Internet resources after they pass authentication.

Figure 382 Network diagram

Configuration prerequisites

Make sure the host, switch, and servers can reach each other.

Make sure the RADIUS server is correctly configured to provide authentication, authorization, and accounting functions. In this example, create a portal user account with the account name **userpt** on the RADIUS server.

Perform the following configuration on the DHCP server:

- Specify the IP address ranges (192.168.1.0/24, 3.3.3.0/24, 2.2.2.0/24) for address allocation.
- Specify the default gateway address 192.168.1.1.
- Specify the leases for the assigned IP addresses and make sure there is a route to the host.

Configuring the switch

1. Add Ethernet ports to VLANs and assign IP addresses to the VLAN interfaces. (Details not shown)
2. Configure the RADIUS authentication server:
 - a. Select **Authentication > RADIUS** from the navigation tree.
The RADIUS server configuration page appears, as shown in [Figure 383](#).
 - b. Select **Authentication Server** as the server type, enter the IP address **1.1.1.2** and port number **1812**, select **active** from the **Primary Server Status** list, and click **Apply**.

Figure 383 Configuring the RADIUS authentication server

RADIUS Server	RADIUS Setup
Server Type:	Authentication Server
Primary Server IP:	1.1.1.2 *
Primary Server UDP Port:	1812 *(1-65535)

Secondary Server IP:	0.0.0.0 *
Secondary Server UDP Port:	1812 *(1-65535)
Secondary Server Status:	block

Items marked with an asterisk(*) are required

Apply

3. Configure a RADIUS accounting server:
On the RADIUS server configuration page, select **Accounting Server** as the server type, and enter the IP address **1.1.1.2** and port number **1813**, select **active** from the **Primary Server Status** list, and click **Apply**.

Figure 384 Configuring a RADIUS accounting server

Secondary Server IP:	0.0.0.0 *
Secondary Server UDP Port:	1813 *(1-65535)
Secondary Server Status:	block

Items marked with an asterisk(*) are required

Apply

4. Configure RADIUS scheme **system** for information exchanges between the device and the RADIUS servers:
 - a. Click the **RADIUS Setup** tab.
 - b. Select **extended** as the server type.
 - c. Select the **Authentication Server Shared Key** box, enter the key **expert**, and then enter the key again in the **Confirm Authentication Shared Key** field.
 - d. Select the **Accounting Server Shared Key** box, enter the key **expert**, and then enter the key again in the **Confirm Accounting Shared Key** field.
 - e. Select **without-domain** as the username format.
 - f. Click **Apply**.

A configuration progress dialog box appears.

- f. After the configuration process is complete, click **Close**.

Figure 389 Configuring the authorization method for the ISP domain

The image shows a web-based configuration interface for AAA. At the top, there are four tabs: 'Domain Setup', 'Authentication', 'Authorization' (which is active), and 'Accounting'. Below the tabs, the title is 'Authorization Configuration of AAA'. There is a dropdown menu 'Select an ISP domain' with 'test' selected. Below this, there are several rows of configuration options. The first row, 'Default AuthZ', is checked. It has a dropdown for the method (set to 'RADIUS'), a dropdown for the name (set to 'system'), and a 'Secondary Method' dropdown. Below this are five unchecked rows: 'LAN-access AuthZ', 'Login AuthZ', 'PPP AuthZ', 'Portal AuthZ', and 'Command AuthZ', each with its own method, name, and secondary method dropdown. At the bottom center, there is an 'Apply' button.

- g. On the **Accounting** tab, select ISP domain **test**, select the **Default Accounting** box, select **RADIUS** from **Default Accounting** list, select **system** from the **Name** list to use it as the accounting scheme, and click **Apply**.

The configuration progress dialog box appears.

- h. After the configuration process is complete, click **Close**.

Verifying the configuration

Before accessing a Web page, user **userpt** is in VLAN 8 (the initial VLAN) and is assigned an IP address on subnet 192.168.1.0/24.

When the user attempts to access a Web page on the Internet, the Web request is redirected to authentication page **http://4.4.4.4/portal/logon.htm**.

The user provides the correct username and password to pass portal authentication and can access Internet resources.

Configuring direct portal authentication

Network requirements

As shown in [Figure 395](#), the host is assigned a public network IP address either manually or through DHCP.

Configure the switch to perform direct portal authentication for users on the host. Before passing portal authentication, users can access only the portal server. After passing portal authentication, they can access Internet resources.

Use the IMC server as the RADIUS server for user authentication, authorization and accounting.

Figure 395 Network diagram

Configuration prerequisites

Make sure the IP address of the access device added on the portal server is the IP address of the interface connected to the host (2.2.2.1 in this example), and the IP address group associated with the access device is the subnet where the host resides (2.2.2.0/24 in this example).

Configure IP addresses for the host, switch, and servers as shown in Figure 395 and make sure they can reach each other.

Make sure the RADIUS server is correctly configured to provide authentication and accounting functions.

Configuring the switch

1. Configure the RADIUS authentication server:
 - a. Select **Authentication > RADIUS** from the navigation tree.
The RADIUS server configuration page appears, as shown in Figure 396.
 - b. Select **Authentication Server** as the server type, enter the IP address **192.168.0.112** and port number **1812**, select **active** from the **Primary Server Status** list, and click **Apply**.

Figure 396 Configuring the RADIUS authentication server

Configuring cross-subnet portal authentication

Network requirements

As shown in Figure 404, configure Switch A to perform cross-subnet portal authentication for users. Before passing portal authentication, the host can access only the portal server. After passing portal authentication, the host can access Internet resources. Use the IMC server as the RADIUS server for user authentication, authorization, and accounting.

Figure 404 Network diagram

Configuration prerequisites

Make sure the IP address of the access device added on the portal server is the IP address of the interface connected to the host (20.20.20.1 in this example), and the IP address group associated with the access device is the subnet where the host resides (8.8.8.0/24 in this example).

Assign IP addresses to the host, switches, and servers as shown in [Figure 404](#) and make sure they can reach each other.

Make sure the RADIUS server is correctly configured to provide authentication and accounting functions for users.

Configuring Switch A

1. Configure the RADIUS authentication server:
 - a. Select **Authentication** > **RADIUS** from the navigation tree.
The RADIUS server configuration page appears, as shown in [Figure 405](#).
 - b. Select **Authentication Server** as the server type, enter the IP address **192.168.0.112** and port number **1812**, select **active** from the **Primary Server Status** list, and click **Apply**.

Figure 405 Configuring the RADIUS authentication server

Configuring Switch B

Configure a default route to subnet 192.168.0.0/24 with the next hop as 20.20.20.1. (Details not shown.)

Configuring RADIUS

RADIUS is a protocol for implementing Authentication, Authorization, and Accounting (AAA). For more information about AAA, see "[Configuring AAA](#)."

Overview

Remote Authentication Dial-In User Service (RADIUS) is a distributed information interaction protocol that uses a client/server model. It can protect networks against unauthorized access and is often used in network environments with requirements for both high security and remote user access.

RADIUS uses UDP as the transport protocol. It uses UDP port 1812 for authentication and UDP port 1813 for accounting.

RADIUS was originally designed for dial-in user access. With the addition of new access methods, RADIUS has been extended to support additional access methods, such as Ethernet and ADSL. RADIUS provides access authentication and authorization services, and its accounting function collects and records network resource usage information.

Client/Server model

The RADIUS client runs on the NASs located throughout the network. It passes user information to RADIUS servers and acts on the responses to, for example, reject or accept user access requests.

The RADIUS server runs on the computer or workstation at the network center and maintains information related to user authentication and network service access. It listens to connection requests, authenticates users, and returns user access control information (for example, rejecting or accepting the user access request) to the clients.

In general, the RADIUS server maintains the following databases: Users, Clients, and Dictionary.

Figure 413 RADIUS server databases

- **Users**—Stores user information, such as the usernames, passwords, applied protocols, and IP addresses.
- **Clients**—Stores information about RADIUS clients, such as shared keys and IP addresses.
- **Dictionary**—Stores RADIUS protocol attributes and their values.

Security and authentication mechanisms

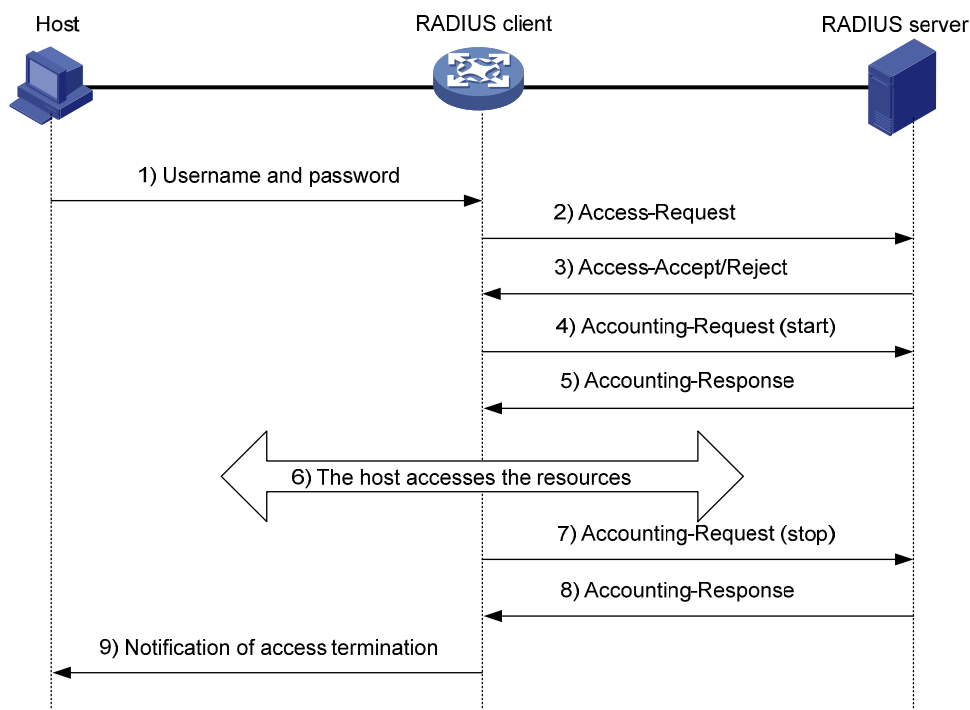

A RADIUS client and the RADIUS server use a shared key to authenticate RADIUS packets and encrypt user passwords that are exchanged between them. The keys are never transmitted over the network. This security mechanism improves the security of RADIUS communication and prevents user passwords from being intercepted on insecure networks.

A RADIUS server supports multiple user authentication methods. A RADIUS server can also act as the client of another AAA server to provide authentication proxy services.

Basic RADIUS message exchange process

Figure 414 illustrates the interactions between the host, the RADIUS client, and the RADIUS server.

Figure 414 Basic RADIUS message exchange process

RADIUS operates in the following manner:

1. The host initiates a connection request that carries the user's username and password to the RADIUS client.
2. Having received the username and password, the RADIUS client sends an authentication request (Access-Request) to the RADIUS server, with the user password encrypted by using the MD5 algorithm and the shared key.
3. The RADIUS server authenticates the username and password. If the authentication succeeds, the server sends back an Access-Accept message containing the user's authorization information. If the authentication fails, the server returns an Access-Reject message.
4. The RADIUS client permits or denies the user according to the returned authentication result. If it permits the user, it sends a start-accounting request (Accounting-Request) to the RADIUS server.
5. The RADIUS server returns an acknowledgement (Accounting-Response) and starts accounting.

6. The user accesses the network resources.
7. The host requests the RADIUS client to tear down the connection and the RADIUS client sends a stop-accounting request (Accounting-Request) to the RADIUS server.
8. The RADIUS server returns an acknowledgement (Accounting-Response) and stops accounting for the user.

RADIUS packet format

RADIUS uses UDP to transmit messages. To ensure smooth message exchange between the RADIUS server and the client, RADIUS uses a series of mechanisms, including the timer management mechanism, the retransmission mechanism, and the backup server mechanism. [Figure 415](#) shows the RADIUS packet format.

Figure 415 RADIUS packet format

Descriptions of the fields are as follows:

- The Code field (1 byte long) indicates the type of the RADIUS packet.

Table 116 Main values of the Code field

Code	Packet type	Description
1	Access-Request	From the client to the server. A packet of this type carries user information for the server to authenticate the user. It must contain the User-Name attribute and can optionally contain the attributes of NAS-IP-Address, User-Password, and NAS-Port.
2	Access-Accept	From the server to the client. If all the attribute values carried in the Access-Request are acceptable, the authentication succeeds, and the server sends an Access-Accept response.
3	Access-Reject	From the server to the client. If any attribute value carried in the Access-Request is unacceptable, the authentication fails, and the server sends an Access-Reject response.
4	Accounting-Request	From the client to the server. A packet of this type carries user information for the server to start or stop accounting for the user. The Acct-Status-Type attribute in the packet indicates whether to start or stop accounting.
5	Accounting-Response	From the server to the client. The server sends a packet of this type to notify the client that it has received the Accounting-Request and has successfully recorded the accounting information.

- The Identifier field (1 byte long) is used to match request packets and response packets and to detect duplicate request packets. Request and response packets of the same type have the same identifier.
- The Length field (2 bytes long) indicates the length of the entire packet, including the Code, Identifier, Length, Authenticator, and Attributes fields. Bytes beyond this length are considered padding and are ignored at the receiver. If the length of a received packet is less than this length, the packet is dropped. The value of this field is in the range 20 to 4096.
- The Authenticator field (16 bytes long) is used to authenticate responses from the RADIUS server and to encrypt user passwords. There are two types of authenticators: request authenticator and response authenticator.
- The Attributes field (variable in length) carries the specific authentication, authorization, and accounting information that defines the configuration details of the request or response. This field may contain multiple attributes, each with three sub-fields:
 - **Type**—(1 byte long) Type of the attribute. It is in the range of 1 to 255. Commonly used RADIUS attributes are defined in RFC 2865, RFC 2866, RFC 2867, and RFC 2868. [Table 117](#) shows a list of the attributes.
 - **Length**—(1 byte long) Length of the attribute in bytes, including the Type, Length, and Value sub-fields.
 - **Value**—(Up to 253 bytes) Value of the attribute. Its format and content depend on the Type and Length sub-fields.

Extended RADIUS attributes

The RADIUS protocol features excellent extensibility. Attribute 26 (Vendor-Specific), an attribute defined in RFC 2865, allows a vendor to define extended attributes to implement functions that the standard RADIUS protocol does not provide.

A vendor can encapsulate multiple sub-attributes in the type-length-value (TLV) format in attribute 26 to provide extended functions. As shown in [Figure 416](#), a sub-attribute encapsulated in attribute 26 consists of the following parts:

- **Vendor-ID**—ID of the vendor. Its most significant byte is 0, and the other three bytes contains a code that is compliant to RFC 1700.
- **Vendor-Type**—Type of the sub-attribute.

- **Vendor-Length**—Length of the sub-attribute.
- **Vendor-Data**—Contents of the sub-attribute.

Figure 416 Format of attribute 26

Protocols and standards

- RFC 2865, *Remote Authentication Dial In User Service (RADIUS)*
- RFC 2866, *RADIUS Accounting*
- RFC 2867, *RADIUS Accounting Modifications for Tunnel Protocol Support*
- RFC 2868, *RADIUS Attributes for Tunnel Protocol Support*
- RFC 2869, *RADIUS Extensions*

Recommended RADIUS configuration procedure

The RADIUS scheme configured through the web interface is named **system**.

If the switch does not contain a RADIUS scheme named **system**, it automatically creates the scheme when you select **Authentication > RADIUS** to enter the RADIUS module.

Step	Remarks
1. Configuring RADIUS authentication servers	<p>Required.</p> <p>Configure the primary and secondary RADIUS authentication servers.</p> <p>By default, no RADIUS authentication server is configured.</p> <p>For more information about the configuration procedure, see "Configuring RADIUS servers."</p>
2. Configuring RADIUS accounting servers	<p>Optional.</p> <p>Configure the primary and secondary RADIUS accounting servers.</p> <p>By default, no RADIUS accounting server is configured.</p> <p>For more information about the configuration procedure, see "Configuring RADIUS servers."</p>
3. Configuring RADIUS communication parameters	<p>Required.</p> <p>Configure the parameters used for information exchange between the switch and RADIUS servers.</p>

Configuring RADIUS servers

1. Select **Authentication** > **RADIUS** from the navigation tree.
The RADIUS server configuration page appears.

Figure 417 RADIUS Server page

RADIUS Server	RADIUS Setup
Server Type:	Authentication Server
Primary Server IP:	0.0.0.0 *
Primary Server UDP Port:	1812 *(1-65535)
Primary Server Status:	block
Secondary Server IP:	0.0.0.0 *
Secondary Server UDP Port:	1812 *(1-65535)
Secondary Server Status:	block

Items marked with an asterisk(*) are required

Apply

2. Configure the RADIUS server parameters as described in [Table 118](#).
3. Click **Apply**.

Table 118 Configuration items

Item	Description
Server Type	Specify the type of the server to be configured: Authentication Server or Accounting Server .
Primary Server IP	Specify the IP address of the primary server. If no primary server is specified, the field displays 0.0.0.0 . To remove the previously configured primary server, enter 0.0.0.0 . The specified IP address of the primary server cannot be the same as that of the secondary server.
Primary Server UDP Port	Specify the UDP port of the primary server. If the IP address of the primary server is not specified or the specified IP address is to be removed, the port number is 1812 for authentication or 1813 for accounting.
Primary Server Status	Set the status of the primary server, including: <ul style="list-style-type: none">• Active—The server is correctly operating.• Blocked—The server is down. If the IP address of the primary server is not specified or the specified IP address is to be removed, the status is Blocked .

Item	Description
Secondary Server IP	<p>Specify the IP address of the secondary server.</p> <p>If no secondary server is specified, the field displays 0.0.0.0.</p> <p>To remove the previously configured secondary server, enter 0.0.0.0.</p> <p>The specified IP address of the secondary server cannot be the same as that of the primary server.</p>
Secondary Server UDP Port	<p>Specify the UDP port of the secondary server.</p> <p>If the IP address of the secondary server is not specified or the specified IP address is to be removed, the port number is 1812 for authentication or 1813 for accounting.</p>
Secondary Server Status	<p>Status of the secondary server, including:</p> <ul style="list-style-type: none"> • Active—The server is correctly operating. • Blocked—The server is down. <p>If the IP address of the secondary server is not specified or the specified IP address is to be removed, the status is Blocked.</p>

Configuring RADIUS communication parameters

1. Select **Authentication** > **RADIUS** from the navigation tree, and then click the **RADIUS Setup** tab.
The RADIUS parameter configuration page appears.

2. Configure the RADIUS communication parameters as described in [Table 119](#).
3. Click **Apply**.

Table 119 Configuration items

Item	Description
Server Type	<p>Specify the type of the RADIUS server supported by the switch, including:</p> <ul style="list-style-type: none"> • Extended—Specifies an extended RADIUS server (offered by IMC). The RADIUS client and RADIUS server communicate using the proprietary RADIUS protocol and packet format. • Standard—Specifies a standard RADIUS server. The RADIUS client and RADIUS server communicate using the standard RADIUS protocol and packet format defined in RFC 2138/2139 or later.
Authentication Server Shared Key Confirm Authentication Shared Key	<p>Specify and confirm the shared key for the authentication server. These two parameters must have the same values.</p>
Accounting Server Shared Key Confirm Accounting Shared Key	<p>Specify and confirm the shared key for the accounting server. These two parameters must have the same values.</p>

Item	Description
NAS-IP	<p>Specify the source IP address for the switch to use in RADIUS packets to be sent to the RADIUS server.</p> <p>Use a loopback interface address instead of a physical interface address as the source IP address. If you use a physical interface and it is down, the response packets from the server cannot reach the switch.</p>
Timeout Interval	Set the RADIUS server response timeout.
Timeout Retransmission Times	<p>Set the maximum number of transmission attempts.</p> <p>The product of the timeout value and the number of retransmission attempts cannot exceed 75.</p>
Realtime-Accounting Interval	<p>Set the real-time accounting interval, whose value must be n times 3 (n is an integer).</p> <p>To implement real-time accounting on users, it is necessary to set the real-time accounting interval. After this parameter is specified, the switch will send the accounting information of online users to the RADIUS server every the specified interval.</p> <p>The value of the real-time accounting interval is related to the requirement on the performance of the NAS and RADIUS server. The smaller the value, the higher the requirement. Set a large value if the number of users is equal to or larger than 1000. Table 120 shows the relationship between the interval value and the number of users.</p>
Realtime-Accounting Packet Retransmission Times	Set the maximum number of real-time accounting request retransmission times.
Stop-Accounting Buffer	Enable or disable buffering stop-accounting requests without responses in the switch.
Stop-Accounting Packet Retransmission Times	Set the maximum number of transmission attempts if no response is received for the stop-accounting packet.
Quiet Interval	Specify the interval the RADIUS servers have to wait before being active
Username Format	<p>Set the format of username sent to the RADIUS server.</p> <p>A username is generally in the format of <i>userid@isp-name</i>, of which <i>isp-name</i> is used by the switch to determine the ISP domain to which a user belongs. If a RADIUS server does not accept a username including an ISP domain name, you can configure the switch to remove the domain name of a username before sending it to the RADIUS server.</p> <ul style="list-style-type: none"> • Without-domain—Remove the domain name of a username that is to be sent to the RADIUS server. • With-domain—Keep the domain name of a username that is to be sent to the RADIUS server.
Unit of Data Flows	<p>Specify the unit for data flows sent to the RADIUS server:</p> <ul style="list-style-type: none"> • Byte • Kilo-byte • Mega-byte • Giga-byte

Item	Description
Unit of Packets	Specify the unit for data packets sent to the RADIUS server: <ul style="list-style-type: none"> One-packet Kilo-packet Mega-packet Giga-packet
Security Policy Server	Specify the IP address of the RADIUS security policy server.

Table 120 Relationship between the real-time accounting interval and the number of users

Number of users	Real-time accounting interval (in minutes)
1 to 99	3
100 to 499	6
500 to 999	12
≥ 1000	≥ 15

RADIUS configuration example

Network requirements

As shown in [Figure 419](#), the RADIUS server runs on IMC. It contains the telnet usernames and passwords, and uses the default authentication port, default accounting port, and the shared key **expert** for packet exchange with the switch.

Configure the switch to implements RADIUS authentication and online time accounting for Telnet users, and to remove the domain name of a username before sending it to the RADIUS server.

Figure 419 Network diagram

Configuration procedure

1. Enable the Telnet server function, and configure the switch to use AAA for Telnet users. (Details not shown.)
2. Configure IP addresses for the interfaces. (Details not shown.)
3. Configure RADIUS scheme **system**:
 - a. Select **Authentication > RADIUS** from the navigation tree.
The RADIUS server configuration page appears.
 - b. Configure the following parameters, as shown in [Figure 420](#).

Select **Authentication Server** as the server type.

Enter **10.110.91.146** as the IP address of the primary authentication server

Enter **1812** as the UDP port of the primary authentication server.

Select **active** as the primary server status.

- c. Click **Apply**.

Figure 420 Configuring the RADIUS authentication server

RADIUS Server	RADIUS Setup
Server Type:	Authentication Server
Primary Server IP:	10.110.91.146 *
Primary Server UDP Port:	1812 *(1-65535)
Primary Server Status:	active
Secondary Server IP:	0.0.0.0 *
Secondary Server UDP Port:	1812 *(1-65535)
Secondary Server Status:	block

Items marked with an asterisk(*) are required

Apply

Configure the RADIUS accounting server.

- a. Select **Authentication > RADIUS** from the navigation tree.

The RADIUS server configuration page appears.

- b. Configure the following parameters, as shown in [Figure 421](#).

Select **Accounting Server** as the server type.

Enter **10.110.91.146** as the IP address of the primary accounting server.

Enter **1813** as the UDP port of the primary accounting server.

Select **active** as the primary server status.

- c. Click **Apply**.

Figure 421 Configuring the RADIUS accounting server

RADIUS Server	RADIUS Setup
Server Type:	Accounting Server
Primary Server IP:	10.110.91.146 *
Primary Server UDP Port:	1813 *(1-65535)
Primary Server Status:	active

Secondary Server UDP Port:	1813 *(1-65535)
Secondary Server Status:	block

Items marked with an asterisk(*) are required

Apply

Configure the RADIUS communication parameters.

- a. Select **Authentication > RADIUS** from the navigation tree and then click the **RADIUS Setup** tab.

The RADIUS parameter configuration page appears.

- b. Configure the following parameters, as shown in [Figure 422](#).

Select **extended** as the server type.

Select the **Authentication Server Shared Key** box and enter **expert**.

Enter **expert** in the **Confirm Authentication Shared Key** field.

Select the **Accounting Server Shared Key** box and enter **expert**.

Enter **expert** in the **Confirm Accounting Shared Key** field.

Select **without-domain** for **Username Format**.

- c. Click **Apply**.

Configuration guidelines

When you configure the RADIUS client, follow these guidelines:

- The specified server status is dynamic information, which cannot be saved in the configuration file. After the switch reboots, the status of servers becomes **active**.
- Accounting for FTP users is not supported.
- If you remove the accounting server used for online users, the switch cannot send real-time accounting requests and stop-accounting messages of the users to the server, and the stop-accounting messages are not buffered locally.
- For the primary and secondary servers (assume only one secondary server exists) in a RADIUS scheme, the switch follows these rules to exchange packets with the servers:
 - If the primary server and secondary server are in the same state, the switch communicates with the primary server.
 - If both the primary server and secondary server are in **active** state, the switch communicates with the primary server. When the primary server becomes unreachable, the switch sets the server's status to **block** and turns to the secondary server for communication. When the quiet timer expires, the switch changes the status of the primary server to **active** while keeping the status of the secondary server unchanged. For authentication and authorization, the switch resumes the communication with the primary server if the primary server has come back into operation; in the case of accounting, however, the switch keeps communicating with the secondary server no matter whether the primary server recovers or not.
 - If one server is in **active** state and the other is in **block** state, the switch only tries to communicate with the server in **active** state, even if the server is unreachable.
 - If both the primary server and secondary server are in **block** state, the switch only communicates with the primary server. In this case, if the primary server is reachable, the switch

changes the primary server's status to **active**. To use the secondary server for communication, you need to manually change the status of the secondary server to **active**; otherwise, no primary/secondary server switchover will take place.

Configuring users and user groups

Overview

You can configure local users and create groups to manage users on the switch series.

A local user represents a set of user attributes configured on a switch (such as the user password, use type, service type, and authorization attribute), and is uniquely identified by the username. For a user requesting a network service to pass local authentication, you must add an entry as required in the local user database of the switch. For more information about local authentication, see "[Configuring AAA](#)."

A user group consists of a group of local users and has a set of local user attributes. You can configure local user attributes for a user group to implement centralized management of user attributes for the local users in the group. All local users in a user group inherit the user attributes of the group, but if you configure user attributes for a local user, the settings of the local user take precedence over the settings for the user group.

By default, every newly added local user belongs to a user group named system, which is automatically created by the system.

Configuring a local user

1. Select **Authentication > Users** from the navigation tree to enter the **Local User** tab, which displays all local users.

ACL	Specify the ACL to be used by the NAS to control the access of users of the user group after the users pass authentication.
User-profile	User profile for the user group. The switch series does not support this option.

Configuring PKI

Overview

The Public Key Infrastructure (PKI) is a hierarchical framework designed for providing information security through public key technologies and digital certificates and verifying the identities of the digital certificate owners.

PKI employs digital certificates, which are bindings of certificate owner identity information and public keys. It allows users to obtain certificates, use certificates, and revoke certificates. By leveraging digital certificates and relevant services like certificate distribution and blacklist publication, PKI supports authenticating the entities involved in communication, and thus guaranteeing the confidentiality, integrity, and non-repudiation of data.

PKI terminology

Digital certificate

A digital certificate is a file signed by a certificate authority (CA) that contains a public key and the related user identity information. A simplest digital certificate contains a public key, an entity name, and a digital signature from the CA. Generally, a digital certificate also includes the validity period of the key, the name of the CA and the sequence number of the certificate. A digital certificate must comply with the international standard of ITU-T_X.509. This document involves local certificate and CA certificate. A local certificate is a digital certificate signed by a CA for an entity. A CA certificate, also known as a "root certificate", is signed by the CA for itself.

CRL

An existing certificate might need to be revoked when, for example, the user name changes, the private key leaks, or the user stops the business. Revoking a certificate will remove the binding of the public key with the user identity information. In PKI, the revocation is made through certificate revocation lists (CRLs). Whenever a certificate is revoked, the CA publishes one or more CRLs to show all certificates that have been revoked. The CRLs contain the serial numbers of all revoked certificates and provide an effective way for checking the validity of certificates.

A CA might publish multiple CRLs when the number of revoked certificates is so large that publishing them in a single CRL might degrade network performance.

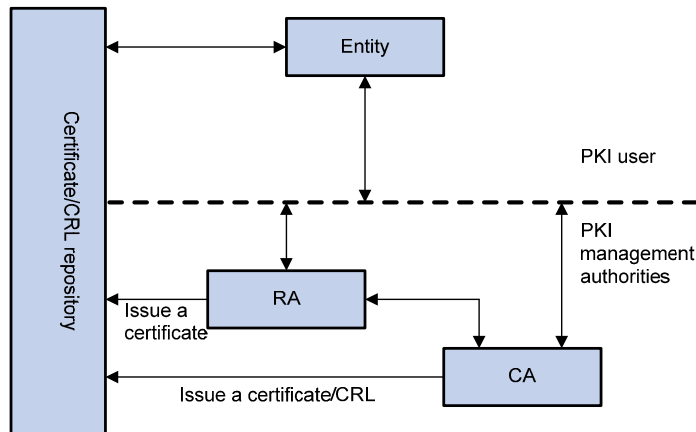

CA policy

A CA policy is a set of criteria that a CA follows in processing certificate requests, issuing and revoking certificates, and publishing CRLs. Usually, a CA advertises its policy in the form of certification practice statement (CPS). A CA policy can be acquired through out-of-band means such as phone, disk, and email. As different CAs might use different methods to check the binding of a public key with an entity, make sure that you understand the CA policy before selecting a trusted CA for certificate request.

PKI architecture

A PKI system consists of entities, a CA, a registration authority (RA) and a PKI repository.

Figure 432 PKI architecture

- **PKI entity**—A PKI entity is an end user or host using PKI certificates. The PKI entity can be an operator, an organization, a device like a router or a switch, or a process running on a computer.
- **CA**—A CA is a trusted authority that issues and manages digital certificates. A CA issues certificates, defines the certificate validity periods, and revokes certificates by publishing CRLs.
- **RA**—A registration authority (RA) is an extended part of a CA or an independent authority. An RA can implement functions including identity authentication, CRL management, key pair generation and key pair backup. It only examines the qualifications of users; it does not sign certificates. Sometimes, a CA assumes the registration management responsibility and no independent RA exists. The PKI standard recommends that an independent RA be used for registration management to achieve higher security of application systems.
- **Repository**—A PKI repository can be a Lightweight Directory Access Protocol (LDAP) server or a common database. It stores and manages information like certificate requests, certificates, keys, CRLs and logs, and it provides a simple query function.

LDAP is a protocol for accessing and managing PKI information. An LDAP server stores user information and digital certificates from the RA server and provides directory navigation service. From an LDAP server, an entity can retrieve digital certificates of its own and other entities.

PKI applications

The PKI technology can meet the security requirements of online transactions. As an infrastructure, PKI has a wide range of applications. Here are some application examples.

- **VPN**—A VPN is a private data communication network built on the public communication infrastructure. A VPN can leverage network layer security protocols (for example, IPsec) in conjunction with PKI-based encryption and digital signature technologies for confidentiality.
- **Secure emails**—PKI can address the email requirements for confidentiality, integrity, authentication, and non-repudiation. A common secure email protocol is Secure/Multipurpose Internet Mail Extensions (S/MIME), which is based on PKI and allows for transfer of encrypted mails with signature.
- **Web security**—The SSL protocol can be used to establish a secure connection between a client and a Web server. During the SSL handshake, both parties can use PKI to identity the peer identity by digital certificates.

PKI operation

The following describes how a PKI entity requests a local certificate from a CA, and how an RA is involved in entity enrollment:

1. A PKI entity submits a certificate request to the CA.
2. The RA verifies the identity of the entity and sends a digital signature containing the identity information and the public key to the CA.
3. The CA verifies the digital signature, approves the application, and issues a certificate.
4. The RA receives the certificate from the CA, sends it to the LDAP server to provide directory navigation service, and notifies the entity that the certificate is successfully issued.
5. The entity retrieves the certificate. With the certificate, the entity can communicate with other entities safely through encryption and digital signature.
6. The entity makes a request to the CA when it needs to revoke its certificate. The CA approves the request, updates the CRLs and publishes the CRLs on the LDAP server.

Configuring PKI

The device supports the following PKI certificate request modes:

- **Manual**—In manual mode, you need to retrieve a CA certificate, generate a local RSA key pair, and submit a local certificate request for an entity.
- **Auto**—In auto mode, an entity automatically requests a certificate through the Simple Certification Enrollment Protocol (SCEP) when it has no local certificate or the present certificate is about to expire.

You can specify the PKI certificate request mode for a PKI domain. Different PKI certificate request modes require different configurations.

Recommended configuration procedure for manually requesting a certificate

Step	Remarks
1. Creating a PKI entity	<p>(Required.)</p> <p>Create a PKI entity and configure the identity information.</p> <p>A certificate is the binding of a public key and the identity information of an entity, where the identity information is identified by an entity distinguished name (DN). A CA identifies a certificate applicant uniquely by an entity DN.</p> <p> IMPORTANT:</p> <p>The DN settings of an entity must be compliant to the CA certificate issue policy for confirming which entity parameters are mandatory or optional. Otherwise, the certificate request might be rejected.</p>

Step	Remarks
2. Creating a PKI domain	<p>(Required.)</p> <p>Create a PKI domain, setting the certificate request mode to Manual.</p> <p>Before requesting a PKI certificate, an entity needs to be configured with some enrollment information, which is referred to as a PKI domain.</p> <p>A PKI domain is intended only for convenience of reference by other applications, and has only local significance.</p>
3. Creating an RSA key pair	<p>(Required.)</p> <p>Generate a local RSA key pair.</p> <p>By default, no local RSA key pair exists.</p> <p>Generating an RSA key pair is an important step in certificate request. The key pair includes a public key and a private key. The private key is kept by the user, and the public key is transferred to the CA along with some other information.</p> <p>! IMPORTANT:</p> <p>If a local certificate already exists, you must remove the certificate before generating a new key pair, so as to keep the consistency between the key pair and the local certificate.</p>
4. Retrieving the CA certificate	<p>(Required.)</p> <p>Certificate retrieval serves the following purposes:</p> <ul style="list-style-type: none"> Locally store the certificates associated with the local security domain for improved query efficiency and reduced query count, Prepare for certificate verification. <p>! IMPORTANT:</p> <p>If a local CA certificate already exists, you cannot perform the CA certificate retrieval operation. This will avoid possible mismatch between certificates and registration information resulting from relevant changes. To retrieve the CA certificate, you need to remove the CA certificate and local certificate first.</p>
5. Requesting a local certificate	<p>(Required.)</p> <p>When requesting a certificate, an entity introduces itself to the CA by providing its identity information and public key, which will be the major components of the certificate.</p> <p>A certificate request can be submitted to a CA in online mode or offline mode.</p> <ul style="list-style-type: none"> In online mode, if the request is granted, the local certificate will be retrieved to the local system automatically. In offline mode, you need to retrieve the local certificate by an out-of-band means. <p>! IMPORTANT:</p> <p>If a local certificate already exists, you cannot perform the local certificate retrieval operation. This will avoid possible mismatch between the local certificate and registration information resulting from relevant changes. To retrieve a new local certificate, you need to remove the CA certificate and local certificate first.</p>

Step	Remarks
	(Optional.)
6. Destroying the RSA key pair	Destroy the existing RSA key pair and the corresponding local certificate. If the certificate to be retrieved contains an RSA key pair, you need to destroy the existing key pair. Otherwise, the retrieving operation will fail.
7. Retrieving and displaying a certificate	(Optional.) Retrieve an existing certificate.
8. Retrieving and displaying a CRL	(Optional.) Retrieve a CRL and display its contents.

Recommended configuration procedure for configuring automatic certificate request

Task	Remarks
	(Required.) Create a PKI entity and configure the identity information. A certificate is the binding of a public key and an entity, where an entity is the collection of the identity information of a user. A CA identifies a certificate applicant by entity. The identity settings of an entity must be compliant to the CA certificate issue policy. Otherwise, the certificate request might be rejected.
1. Creating a PKI entity	
	(Required.) Create a PKI domain, setting the certificate request mode to Auto . Before requesting a PKI certificate, an entity needs to be configured with some enrollment information, which is referred to as a PKI domain. A PKI domain is intended only for convenience of reference by other applications, and has only local significance.
2. Creating a PKI domain	
	(Optional.) Destroy the existing RSA key pair and the corresponding local certificate. If the certificate to be retrieved contains an RSA key pair, you need to destroy the existing key pair. Otherwise, the retrieving operation will fail.
3. Destroying the RSA key pair	
4. Retrieving and displaying a certificate	(Optional.) Retrieve an existing certificate.
5. Retrieving and displaying a CRL	(Optional.) Retrieve a CRL and display its contents.

Creating a PKI entity

1. Select **Authentication** > **PKI** from the navigation tree.
The PKI entity list page is displayed by default.

Figure 433 PKI entity list

Entity	Domain	Certificate	CRL						
Entity Name	Common Name	FQDN	Country/Region Code	State	Locality	Organization	Organization Unit	IP Address	Operation
entity1	aaa		CN					1.1.1.10

CRL Update Period: hours (1-720)

CRL URL: (1-127 Chars.)

Items marked with an asterisk(*) are required

5. Configure the parameters as described in [Table 124](#).

6. Click **Apply**.

Table 124 Configuration items

Item	Description
Domain Name	Enter the name for the PKI domain.
CA Identifier	Enter the identifier of the trusted CA. An entity requests a certificate from a trusted CA. The trusted CA takes the responsibility of certificate registration, distribution, and revocation, and query. In offline mode, this item is optional. In other modes, this item is required.
Entity Name	Select the local PKI entity. When submitting a certificate request to a CA, an entity needs to show its identity information. Available PKI entities are those that have been configured.

Item	Description
Institution	<p>Select the authority for certificate request.</p> <ul style="list-style-type: none"> • CA—Requests a certificate from a CA. • RA—Requests a certificate from an RA. <p>RA is recommended.</p>
Requesting URL	<p>Enter the URL of the RA.</p> <p>The entity will submit the certificate request to the server at this URL through the SCEP protocol. The SCEP protocol is intended for communication between an entity and an authentication authority.</p> <p>In offline mode, this item is optional. In other modes, this item is required.</p> <p> IMPORTANT:</p> <p>This item does not support domain name resolution.</p>
LDAP IP	Enter the IP address, port number and version of the LDAP server.
Port	In a PKI system, the storage of certificates and CRLs is a crucial problem, which is usually addressed by deploying an LDAP server.
Version	
Request Mode	Select the online certificate request mode, which can be auto or manual.
Password	Set a password for certificate revocation and re-enter it for confirmation.
Confirm Password	The two boxes are available only when the certificate request mode is set to Auto .
Fingerprint Hash	<p>Specify the fingerprint used for verifying the CA root certificate.</p> <p>After receiving the root certificate of the CA, an entity needs to verify the fingerprint of the root certificate, namely, the hash value of the root certificate content. This hash value is unique to every certificate. If the fingerprint of the root certificate does not match the one configured for the PKI domain, the entity will reject the root certificate.</p> <ul style="list-style-type: none"> • If you specify MD5 as the hash algorithm, enter an MD5 fingerprint. The fingerprint must a string of 32 characters in hexadecimal notation. • If you specify SHA1 as the hash algorithm, enter an SHA1 fingerprint. The fingerprint must a string of 40 characters in hexadecimal notation.
Fingerprint	<p> IMPORTANT:</p> <p>The fingerprint must be configured if you specify the certificate request mode as Auto. If you specify the certificate request mode as Manual, you can leave the fingerprint settings null. If you do not configure the fingerprint, the entity will not verify the CA root certificate and you yourself must make sure that the CA server is trusted.</p>
Polling Count	Set the polling interval and attempt limit for querying the certificate request status.
Polling Interval	After an entity makes a certificate request, the CA might need a long period of time if it verifies the certificate request in manual mode. During this period, the applicant needs to query the status of the request periodically to get the certificate as soon as possible after the certificate is signed.
Enable CRL Checking	Select this box to specify that CRL checking is required during certificate verification.
CRL Update Period	<p>Enter the CRL update period, that is, the interval at which the PKI entity downloads the latest CRLs.</p> <p>This item is available after you click the Enable CRL Checking box.</p> <p>By default, the CRL update period depends on the next update field in the CRL file.</p>

Item	Description
CRL URL	Enter the URL of the CRL distribution point. When the URL of the CRL distribution point is not set, you should acquire the CA certificate and a local certificate, and then acquire a CRL through SCEP.

Creating an RSA key pair

1. Select **Authentication** > **PKI** from the navigation tree.
2. Click the **Certificate** tab.

Retrieving and displaying a certificate

You can retrieve an existing CA certificate or local certificate from the CA server and save it locally. To do so, you can use offline mode or online. In offline mode, you must retrieve a certificate by an out-of-band means like FTP, disk, email and then import it into the local PKI system. By default, the retrieved certificate is saved in a file under the root directory of the device, and the filename is *domain-name_ca.cer* for the CA certificate, or *domain-name_local.cer* for the local certificate.

To retrieve a certificate:

1. Select **Authentication** > **PKI** from the navigation tree.
2. Click the **Certificate** tab.
3. Click **Retrieve Cert.**

Enable Offline Mode	Select this box to request a certificate in offline mode, that is, by an out-of-band means like FTP, disk, or email.

5. Click **Apply**.

If you select the online mode, the system gives a prompt that certificate request has been submitted. In this case, click **OK** to finish the operation. If you select the offline mode, the offline certificate request information page appears. In this case, you must submit the information by an out-of-band way to the CA to request a local certificate.

Serial Number	Serial number of the revoked certificate
Revocation Date	Certificate revocation date

PKI configuration example

Network requirements

As shown in Figure 446, configure the switch that acts as the PKI entity, so that:

- The switch submits a local certificate request to the CA server, which runs the RSA Keon software.
- The switch retrieves CRLs for certificate verification.

Figure 446 Network diagram

Configuring the CA server

1. Create a CA server named **myca**:

In this example, you must first configure the basic attributes of **Nickname** and **Subject DN** on the CA server: the nickname is the name of the trusted CA, and the subject DN is the DN attributes of the CA, including the common name (CN), organization unit (OU), organization (O), and country (C). Leave the default values of the other attributes.

2. Configure extended attributes:

After configuring the basic attributes, you need to perform configuration on the **Jurisdiction Configuration** page of the CA server. This includes selecting the proper extension profiles, enabling the SCEP autovetting function, and adding the IP address list for SCEP autovetting.

3. Configure the CRL publishing behavior:

After completing the configuration, you need to perform CRL related configurations.

In this example, select the local CRL publishing mode of HTTP and set the HTTP URL to `http://4.4.4.133:447/myca.crl`.

After the configuration, make sure that the system clock of the switch is synchronous to that of the CA, so that the switch can request certificates and retrieve CRLs correctly.

Configuring the switch

1. Create a PKI entity:
 - a. Select **Authentication > PKI** from the navigation tree.
The PKI entity list page is displayed by default.
 - b. Click **Add**.
 - c. Enter **aaa** as the PKI entity name, enter **ac** as the common name, and click **Apply**.

Figure 447 Creating a PKI entity

Entity	Domain	Certificate	CRL
--------	--------	-------------	-----

Add PKI Entity

Entity Name:	<input type="text" value="aaa"/>	*(1-15 Chars.)
Common Name:	<input type="text" value="ac"/>	*(1-31 Chars.)
IP Address:	<input type="text"/>	
FQDN:	<input type="text"/>	(1-127 Chars.)
Country/Region Code:	<input type="text"/>	(Country/Region name symbol, two characters compliant to ISO 3166 standard.)
State:	<input type="text"/>	(1-31 Chars.)

Organization:	<input type="text"/>	(1-31 Chars.)
Organization Unit:	<input type="text"/>	(1-31 Chars.)

Items marked with an asterisk(*) are required

2. Create a PKI domain:

- a. Click the **Domain** tab.
- b. Click **Add**.

The page in Figure 448 appears.

- c. Enter **torsa** as the PKI domain name, enter **myca** as the CA identifier, select **aaa** as the local entity, select **CA** as the authority for certificate request, enter **http://4.4.4.133:446/c95e970f632d27be5e8cbf80e971d9c4a9a93337** as the URL for certificate request (the URL must be in the format of http://host:port/Issuing Jurisdiction ID, where Issuing Jurisdiction ID is the hexadecimal string generated on the CA), and select **Manual** as the certificate request mode.
- d. Click the collapse button before **Advanced Configuration**.
- e. In the advanced configuration area, click the **Enable CRL Checking** box, and enter **http://4.4.4.133:447/myca.crl** as the CRL URL.
- f. Click **Apply**.

A dialog box appears, asking "Fingerprint of the root certificate not specified. No root certificate validation will occur. Continue?"
- g. Click **OK**.

torsa		Retrieve CRL	View CRL

Verifying the configuration

After the configuration, select **Authentication > PKI > Certificate** from the navigation tree to view detailed information about the retrieved CA certificate and local certificate, or select **Authentication > PKI > CRL** from the navigation tree to view detailed information about the retrieved CRL.

Configuration guidelines

When you configure PKI, follow these guidelines:

- Make sure the clocks of entities and the CA are synchronous. Otherwise, the validity period of certificates will be abnormal.
- The Windows 2000 CA server has some restrictions on the data length of a certificate request. If the PKI entity identity information in a certificate request goes beyond a certain limit, the server will not respond to the certificate request.
- The SCEP plug-in is required when you use the Windows Server as the CA. In this case, you need to specify **RA** as the authority for certificate request when you configure the PKI domain.
- The SCEP plug-in is not required when you use the RSA Keon software as the CA. In this case, you need to specify **CA** as the authority for certificate request when you configure the PKI domain.

Configuring authorized IP

The authorized IP function associates the HTTP or Telnet service with an ACL to filter the requests of clients. Only the clients that pass the ACL filtering can access the device.

Configuration procedure

1. Select **Security > Authorized IP** from the navigation tree.
2. Click the **Setup** tab to enter the authorized IP configuration page.

Figure 453 Authorized IP configuration page

Rule ID	Operation	Description	Time Range
---------	-----------	-------------	------------

3. Configure authorized IP as described in Table 128.
4. Click **Apply**.

Table 128 Configuration items

Item		Description
Telnet	IPv4 ACL	Associate the Telnet service with an IPv4 ACL. You can configure the IPv4 ACL to be selected by selecting QoS > ACL IPv4 .
	IPv6 ACL	Associate the Telnet service with an IPv6 ACL. You can configure the IPv6 ACL to be selected by selecting QoS > ACL IPv6 .
Web (HTTP)	IPv4 ACL	Associate the HTTP service with an IPv4 ACL. You can configure the IPv4 ACL to be selected by selecting QoS > ACL IPv4 .

Authorized IP configuration example

Network requirements

In Figure 454, configure Switch to deny Telnet and HTTP requests from Host A, and permit Telnet and HTTP requests from Host B.

Figure 454 Network diagram

Configuration procedure

1. Create an ACL:
 - a. Select **QoS > ACL IPv4** from the navigation tree.
 - b. Click the **Create** tab.
 - c. Enter **2001** for **ACL Number**.
 - d. Click **Apply**.

Configuring port isolation

Overview

Layer 2 traffic isolation is typically achieved by assigning ports to different VLANs. To save VLAN resources, port isolation is introduced to isolate ports within a VLAN, allowing for great flexibility and security.

The switch series supports only one isolation group that is created automatically by the system as isolation group 1. You can neither remove the isolation group nor create other isolation groups on the switches.

There is no restriction on the number of ports assigned to the isolation group.

Layer 2 traffic is isolated between ports from different VLANs. Within the same VLAN, Layer 2 data transmission between ports within and outside the isolation group is supported.

Configuring the isolation group

1. Select **Security > Port Isolate Group** from the navigation tree.
2. Click the **Port Setup** tab.

Figure 458 Configuring a port isolation group

The screenshot shows the 'Port Setup' configuration page. At the top, there are two tabs: 'Summary' and 'Port Setup'. Below the tabs, the 'Config type' section has two radio buttons: 'Isolated port' (selected) and 'Uplink port'. The 'Select port(s)' section shows a grid of port numbers 1 through 8, with port 3 selected. Below this, the 'Aggregation ports' section shows 'BAGG1' with 'Select All' and 'Select None' buttons. The 'Isolated port' section has a text box containing 'GE1/0/3'. The 'Uplink port' section is empty. An 'Apply' button is at the bottom right.

3. Configure the port isolation group as described in [Table 129](#).
4. Click **Apply**.

Table 129 Configuration items

Item	Description
Config type	<p>Specify the role of the port or ports in the isolation group:</p> <ul style="list-style-type: none"> Isolated port—Assigns the port or ports to the isolation group as an isolated port or ports. Uplink port—Assigns the port to the isolation group as the uplink port. This option is not available for the switch series.
Select port(s)	<p>Select the ports you want to assign to the isolation group.</p> <p>You can click ports on the chassis front panel for selection. If aggregate interfaces are configured, they will appear under the chassis panel for selection.</p>

Port isolation configuration example

Network requirements

As shown in [Figure 459](#):

- Campus network users Host A, Host B, and Host C are connected to GigabitEthernet 1/0/2, GigabitEthernet 1/0/3, and GigabitEthernet 1/0/4 of Switch.
- Switch is connected to the external network through GigabitEthernet 1/0/1.
- GigabitEthernet 1/0/1, GigabitEthernet 1/0/2, GigabitEthernet 1/0/3, and GigabitEthernet 1/0/4 belong to the same VLAN.

Configure Host A, Host B, and Host C to access the external network but to be isolated from one another on Layer 2.

Figure 459 Networking diagram

Configuring the switch

1. Assign GigabitEthernet 1/0/2, GigabitEthernet 1/0/3, and GigabitEthernet 1/0/4 to the isolation group:
 - a. Select **Security > Port Isolate Group** from the navigation tree.
 - b. Click the **Port Setup** tab to enter the page shown in [Figure 460](#).
 - c. Select **Isolated port** for **Config Type**.

- d. Select **2**, **3**, and **4** on the chassis front panel. The numbers represent ports GigabitEthernet 1/0/2, GigabitEthernet 1/0/3, and GigabitEthernet 1/0/4, respectively.

Configuring ACLs

Unless otherwise stated, ACLs refer to both IPv4 and IPv6 ACLs throughout this document.

Overview

An access control list (ACL) is a set of rules (or permit or deny statements) for identifying traffic based on criteria such as source IP address, destination IP address, and port number.

ACLs are primarily used for packet filtering. You can use ACLs in QoS, security, routing, and other feature modules for identifying traffic. The packet drop or forwarding decisions varies with the modules that use ACLs.

ACL categories

Category	ACL number	IP version	Match criteria
Basic ACLs	2000 to 2999	IPv4	Source IPv4 address.
		IPv6	Source IPv6 address.
Advanced ACLs	3000 to 3999	IPv4	Source/destination IPv4 address, protocol number, and other Layer 3 and Layer 4 header fields.
		IPv6	Source/destination IPv6 address, protocol number, and other Layer 3 and Layer 4 header fields.
Ethernet frame header ACLs	4000 to 4999	N/A	Layer 2 header fields, such as source and destination MAC addresses, 802.1p priority, and link layer protocol type

Match order

The rules in an ACL are sorted in certain order. When a packet matches a rule, the device stops the match process and performs the action defined in the rule. If an ACL contains overlapping or conflicting rules, the matching result and action to take depend on the rule order.

The following ACL match orders are available:

- **Config**—Sorts ACL rules in ascending order of rule ID. A rule with a lower ID is matched before a rule with a higher ID. If you use this method, check the rule content and order carefully.
- **Auto**—Sorts ACL rules in depth-first order. Depth-first ordering ensures that any subset of a rule is always matched before the rule. [Table 130](#) lists the sequence of tie breakers that depth-first ordering uses to sort rules for each type of ACL.

Table 130 Depth-first match for ACLs

ACL category	Sequence of tie breakers
IPv4 basic ACL	<ol style="list-style-type: none"> 1. More 0s in the source IP address wildcard (more 0s means a narrower IP address range). 2. Smaller rule ID.
IPv4 advanced ACL	<ol style="list-style-type: none"> 1. Specific protocol number. 2. More 0s in the source IP address wildcard mask 3. More 0s in the destination IP address wildcard 4. Narrower TCP/UDP service port number range. 5. Smaller ID.
IPv6 basic ACL	<ol style="list-style-type: none"> 1. Longer prefix for the source IP address (a longer prefix means a narrower IP address range). 2. Smaller ID.
IPv6 advanced ACL	<ol style="list-style-type: none"> 1. Specific protocol number. 2. Longer prefix for the source IPv6 address. 3. Longer prefix for the destination IPv6 address. 4. Narrower TCP/UDP service port number range. 5. Smaller ID.
Ethernet frame header ACL	<ol style="list-style-type: none"> 1. More 1s in the source MAC address mask (more 1s means a smaller MAC address). 2. More 1s in the destination MAC address mask. 3. Smaller ID.

A wildcard mask, also called an inverse mask, is a 32-bit binary number represented in dotted decimal notation. In contrast to a network mask, the 0 bits in a wildcard mask represent "do care" bits, and the 1 bits represent "don't care" bits. If the "do care" bits in an IP address are identical to the "do care" bits in an IP address criterion, the IP address matches the criterion. All "don't care" bits are ignored. The 0s and 1s in a wildcard mask can be noncontiguous. For example, 0.255.0.255 is a valid wildcard mask.

Rule numbering

ACL rules can be manually numbered or automatically numbered. This section describes how automatic ACL rule numbering works.

Rule numbering step

If you do not assign an ID to the rule you are creating, the system automatically assigns it a rule ID. The rule numbering step sets the increment by which the system automatically numbers rules. For example, the default ACL rule numbering step is 5. If you do not assign IDs to rules you are creating, they are automatically numbered 0, 5, 10, 15, and so on. The wider the numbering step, the more rules you can insert between two rules.

By introducing a gap between rules rather than contiguously numbering rules, you have the flexibility of inserting rules in an ACL. This feature is important for a config-order ACL, where ACL rules are matched in ascending order of rule ID.

Automatic rule numbering and renumbering

The ID automatically assigned to an ACL rule takes the nearest higher multiple of the numbering step to the current highest rule ID, starting with 0.

For example, if the numbering step is 5 (the default), and there are five ACL rules numbered 0, 5, 9, 10, and 12, the newly defined rule is numbered 15. If the ACL does not contain any rule, the first rule is numbered 0.

Whenever the step changes, the rules are renumbered, starting from 0. For example, if there are five rules numbered 5, 10, 13, 15, and 20, changing the step from 5 to 2 causes the rules to be renumbered 0, 2, 4, 6, and 8.

Implementing time-based ACL rules

You can implement ACL rules based on the time of day by applying a time range to them. A time-based ACL rule takes effect only in any time periods specified by the time range.

The following basic types of time range are available:

- **Periodic time range**—Recurrs periodically on a day or days of the week.
- **Absolute time range**—Represents only a period of time and does not recur.

IPv4 fragments filtering with ACLs

Traditional packet filtering matches only first fragments of IPv4 packets, and allows all subsequent non-first fragments to pass through. Attackers can fabricate non-first fragments to attack networks.

To avoid the risks, the HP ACL implementation does the follows:

- Filters all fragments by default, including non-first fragments.
- Allows for matching criteria modification, for example, filters non-first fragments only.

Configuration guidelines

When you configure an ACL, follow these guidelines:

- You cannot add a rule with, or modify a rule to have, the same permit/deny statement as an existing rule in the ACL.
- You can only modify the existing rules of an ACL that uses the match order of **config**. When modifying a rule of such an ACL, you can choose to change just some of the settings, in which case the other settings remain the same.

Recommended ACL configuration procedures

Recommended IPv4 ACL configuration procedure

Step	Remarks
1. Configuring a time range	Optional. Add a time range. A rule referencing a time range takes effect only during the specified time range.

Step	Remarks
2. Adding an IPv4 ACL	Required. Add an IPv4 ACL. The category of the added ACL depends on the ACL number that you specify.
3. Configuring a rule for a basic IPv4 ACL	Required. Complete one of the following tasks according to the ACL category.
4. Configuring a rule for an advanced IPv4 ACL	
5. Configuring a rule for an Ethernet frame header ACL	

Recommended IPv6 ACL configuration procedure

Step	Remarks
1. Configuring a time range	Optional. Add a time range. A rule referencing a time range takes effect only during the specified time range.
2. Adding an IPv6 ACL	Required. Add an IPv6 ACL. The category of the added IPv6 ACL depends on the ACL number that you specify.
3. Configuring a rule for a basic IPv6 ACL	Required. Complete one of the tasks according to the ACL category.
4. Configuring a rule for an advanced IPv6 ACL	

Configuring a time range

1. Select **QoS > Time Range** from the navigation tree.
2. Click the **Create** tab.

Figure 462 Adding a time range

Configuring QoS

Introduction to QoS

Quality of Service (QoS) reflects the ability of a network to meet customer needs. In an internet, QoS evaluates the ability of the network to forward packets of different services.

The evaluation can be based on different criteria because the network provides various services. Generally, QoS performance is measured with respect to bandwidth, delay, jitter, and packet loss ratio during packet forwarding process.

Networks without QoS guarantee

On traditional IP networks without QoS guarantee, devices treat all packets equally and handle them using the first in first out (FIFO) policy. All packets share the resources of the network and devices. How many resources the packets can obtain completely depends on the time they arrive. This service is called "best-effort". It delivers packets to their destinations as possibly as it can, without any guarantee for delay, jitter, packet loss ratio, and so on.

This service policy is only suitable for applications insensitive to bandwidth and delay, such as Word Wide Web (WWW) and email.

QoS requirements of new applications

The Internet has been growing along with the fast development of networking technologies.

Besides traditional applications such as WWW, email and FTP, network users are experiencing new services, such as tele-education, telemedicine, video telephone, videoconference and Video-on-Demand (VoD). Enterprise users expect to connect their regional branches together with VPN technologies to carry out operational applications, for instance, to access the database of the company or to monitor remote devices through Telnet.

These new applications all have special requirements for bandwidth, delay, and jitter. For example, videoconference and VoD require high bandwidth, low delay and jitter. As for mission-critical applications, such as transactions and Telnet, they do not require high bandwidth but do require low delay and preferential service during congestion.

The emerging applications demand higher service performance of IP networks. Better network services during packets forwarding are required, such as providing dedicated bandwidth, reducing packet loss ratio, managing and avoiding congestion, and regulating network traffic. To meet these requirements, networks must provide more improved services.

Congestion: causes, impacts, and countermeasures

Network congestion is a major factor contributed to service quality degrading on a traditional network. Congestion is a situation where the forwarding rate decreases due to insufficient resources, resulting in extra delay.

Causes

Congestion easily occurs in complex packet switching circumstances in the Internet. Figure 470 shows two common cases:

Figure 470 Traffic congestion causes

- The traffic enters a device from a high speed link and is forwarded over a low speed link.
- The packet flows enter a device from several incoming interfaces and are forwarded out of an outgoing interface, whose rate is smaller than the total rate of these incoming interfaces.

When traffic arrives at the line speed, a bottleneck is created at the outgoing interface causing congestion.

Besides bandwidth bottlenecks, congestion can be caused by resource shortage in various forms such as insufficient processor time, buffer, and memory, and by network resource exhaustion resulting from excessive arriving traffic in certain periods.

Impacts

Congestion brings these negative results:

- Increased delay and jitter during packet transmission
- Decreased network throughput and resource use efficiency
- Network resource (memory in particular) exhaustion and even system breakdown

It is obvious that congestion hinders resource assignment for traffic and degrades service performance. Congestion is unavoidable in switched networks and multi-user application environments. To improve the service performance of your network, you must address the congestion issues.

Countermeasures

A simple solution for congestion is to increase network bandwidth, however, it cannot solve all the problems that cause congestion because you cannot increase network bandwidth infinitely.

A more effective solution is to provide differentiated services for different applications through traffic control and resource allocation. In this way, resources can be used more effectively. During resources allocation and traffic control, the direct or indirect factors that might cause network congestion should be controlled to reduce the probability of congestion. Once congestion occurs, resource allocation should be performed according to the characteristics and demands of applications to minimize the effects of congestion.

End-to-end QoS

Figure 471 End-to-end QoS model

As shown in [Figure 471](#), traffic classification, traffic policing, traffic shaping, congestion management, and congestion avoidance are the foundations for a network to provide differentiated services. Mainly they implement the following functions:

- Traffic classification uses certain match criteria to organize packets with different characteristics into different classes. Traffic classification is usually applied in the inbound direction of a port.
- Traffic policing polices particular flows entering or leaving a device according to configured specifications and can be applied in both inbound and outbound directions of a port. When a flow exceeds the specification, some restriction or punishment measures can be taken to prevent overconsumption of network resources.
- Traffic shaping proactively adjusts the output rate of traffic to adapt traffic to the network resources of the downstream device and avoid unnecessary packet drop and congestion. Traffic shaping is usually applied in the outbound direction of a port.
- Congestion management provides a resource scheduling policy to arrange the forwarding sequence of packets when congestion occurs. Congestion management is usually applied in the outbound direction of a port.
- Congestion avoidance monitors the usage status of network resources and is usually applied in the outbound direction of a port. As congestion becomes worse, it actively reduces the amount of traffic by dropping packets.

Among these QoS technologies, traffic classification is the basis for providing differentiated services. Traffic policing, traffic shaping, congestion management, and congestion avoidance manage network traffic and resources in different ways to realize differentiated services.

This section is focused on traffic classification, and the subsequent sections will introduce the other technologies in details.

Traffic classification

When defining match criteria for classifying traffic, you can use IP precedence bits in the type of service (ToS) field of the IP packet header, or other header information such as IP addresses, MAC addresses, IP protocol field and port numbers. You can define a class for packets with the same quintuple (source address, source port number, protocol number, destination address and destination port number for example), or for all packets to a certain network segment.

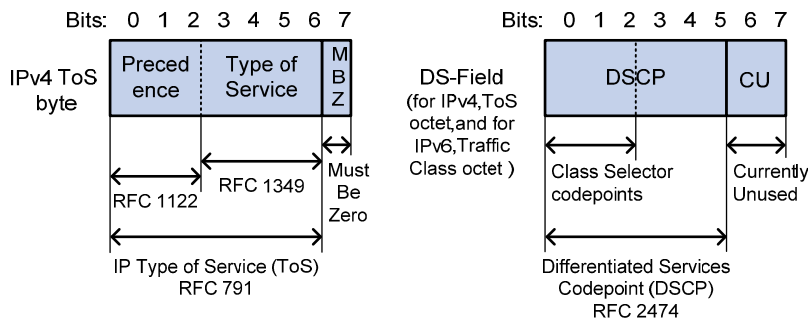

When packets are classified on the network boundary, the precedence bits in the ToS field of the IP packet header are generally re-set. In this way, IP precedence can be directly used to classify the packets in the network. IP precedence can also be used in queuing to prioritize traffic. The downstream network can either use the classification results from its upstream network or classify the packets again according to its own criteria.

To provide differentiated services, traffic classes must be associated with certain traffic control actions or resource allocation actions. What traffic control actions to use depends on the current phase and the resources of the network. For example, CAR polices packets when they enter the network; GTS is performed on packets when they flow out of the node; queue scheduling is performed when congestion happens; congestion avoidance measures are taken when the congestion deteriorates.

Packet precedences

IP precedence and DSCP values

Figure 472 ToS field and DS field

As shown in Figure 472, the ToS field of the IP header contains 8 bits: the first 3 bits (0 to 2) represent IP precedence from 0 to 7; the subsequent 4 bits (3 to 6) represent a ToS value from 0 to 15. According to RFC 2474, the ToS field of the IP header is redefined as the differentiated services (DS) field, where a differentiated services code point (DSCP) value is represented by the first 6 bits (0 to 5) and is in the range 0 to 63. The remaining 2 bits (6 and 7) are reserved.

802.1p priority

802.1p priority lies in Layer 2 packet headers and applies to occasions where Layer 3 header analysis is not needed and QoS must be assured at Layer 2.

Figure 473 An Ethernet frame with an 802.1Q tag header

As shown in [Figure 473](#), the 4-byte 802.1Q tag header consists of the tag protocol identifier (TPID, 2 bytes in length), whose value is 0x8100, and the tag control information (TCI, 2 bytes in length). [Figure 474](#) presents the format of the 802.1Q tag header. The priority in the 802.1Q tag header is called "802.1p priority", because its use is defined in IEEE 802.1p. [Table 141](#) presents the values for 802.1p priority.

Figure 474 802.1Q tag header

Queue scheduling

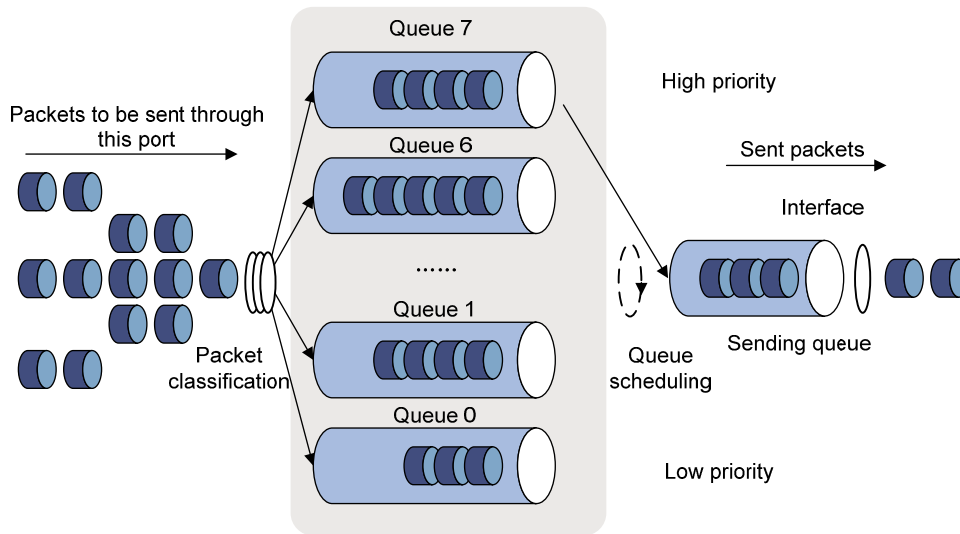

In general, congestion management uses queuing technology. The system uses a certain queuing algorithm for traffic classification, and then uses a certain precedence algorithm to send the traffic. Each queuing algorithm handles a particular network traffic problem and has significant impacts on bandwidth resource assignment, delay, and jitter.

In this section, two common hardware queue scheduling algorithms Strict Priority (SP) queuing and Weighted Round Robin (WRR) queuing are introduced.

SP queuing

SP queuing is designed for mission-critical applications, which require preferential service to reduce response delay when congestion occurs.

Figure 475 SP queuing

A typical switch provides eight queues per port. As shown in [Figure 475](#), SP queuing classifies eight queues on a port into eight classes, numbered 7 to 0 in descending priority order.

SP queuing schedules the eight queues strictly according to the descending order of priority. It sends packets in the queue with the highest priority first. When the queue with the highest priority is empty, it sends packets in the queue with the second highest priority, and so on. You can assign mission-critical packets to the high priority queue to make sure that they are always served first and common service (such as Email) packets to the low priority queues to be transmitted when the high priority queues are empty.

The disadvantage of SP queuing is that packets in the lower priority queues cannot be transmitted if the higher priority queues have packets. This causes lower priority traffic to starve to death.

WRR queuing

WRR (Weighted Round Robin) queuing schedules all the queues in turn to make sure that every queue can be served for a certain time, as shown in [Figure 476](#).

Figure 476 WRR queuing

A typical switch provides eight output queues per port. WRR assigns each queue a weight value (represented by w_7 , w_6 , w_5 , w_4 , w_3 , w_2 , w_1 , or w_0) to decide the proportion of resources assigned to the queue. On a 100 Mbps port, you can set the weight values of WRR queuing to 50, 30, 10, 10, 50, 30, 10, and 10 (corresponding to w_7 , w_6 , w_5 , w_4 , w_3 , w_2 , w_1 , and w_0 , respectively). In this way, the queue with the lowest priority is assured of at least 5 Mbps of bandwidth, and the disadvantage of SP queuing (that packets in low-priority queues might fail to be served for a long time) is avoided.

Another advantage of WRR queuing is that while the queues are scheduled in turn, the service time for each queue is not fixed. If a queue is empty, the next queue will be scheduled immediately. This improves bandwidth resource use efficiency.

All the queues are scheduled by WRR. You can assign the output queues to WRR priority queue group 1 and WRR priority queue group 2. Round robin queue scheduling is performed for group 1 first. If group 1 is empty, round robin queue scheduling is performed for group 2.

You can implement SP+WRR queue scheduling on a port by assigning some queues on the port to the SP scheduling group when you configure WRR. Packets in the SP scheduling group are scheduled preferentially by SP. When the SP scheduling group is empty, the other queues are scheduled by WRR.

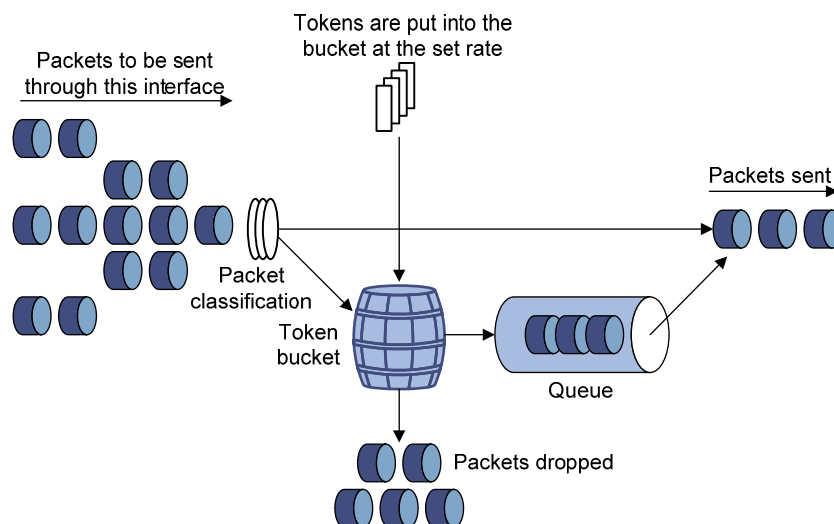

Traffic shaping

Traffic shaping shapes the outbound traffic.

Generic traffic shaping (GTS) limits the outbound traffic rate by buffering exceeding traffic. You can use traffic shaping to adapt the traffic output rate on a device to the input traffic rate of its connected device to avoid packet loss.

The difference between traffic policing and GTS is that packets to be dropped with traffic policing are retained in a buffer or queue with GTS, as shown in [Figure 477](#). When enough tokens are in the token bucket, the buffered packets are sent at an even rate. Traffic shaping can result in additional delay and traffic policing does not.

Figure 477 GTS

For example, in [Figure 478](#), Device B performs traffic policing on packets from Device A and drops packets exceeding the limit. To avoid packet loss, you can perform traffic shaping on the outgoing interface of Device A so packets exceeding the limit are cached in Device A. Once resources are released, traffic shaping takes out the cached packets and sends them out.

Figure 478 GTS application

Rate limit

Rate limit is a traffic control method using token buckets. The rate limit of a physical interface specifies the maximum rate for forwarding packets (including critical packets). Rate limit can limit all the incoming or outgoing packets of physical interface.

Traffic evaluation and token bucket

A token bucket can be considered as a container holding a certain number of tokens. The system puts tokens into the bucket at a set rate. When the token bucket is full, the extra tokens will overflow.

Figure 479 Evaluate traffic with the token bucket

The evaluation for the traffic specification is based on whether the number of tokens in the bucket can meet the need of packet forwarding. If the number of tokens in the bucket is enough to forward the packets (usually, one token is associated with a 1-bit forwarding authority), the traffic conforms to the specification, and the traffic is called "conforming traffic"; otherwise, the traffic does not conform to the specification, and the traffic is called "excess traffic".

A token bucket has the following configurable parameters:

- **Mean rate**—Rate at which tokens are put into the bucket, or the permitted average rate of traffic. It is usually set to the committed information rate (CIR).

- **Burst size**—The capacity of the token bucket, or the maximum traffic size permitted in each burst. It is usually set to the committed burst size (CBS). The set burst size must be greater than the maximum packet size.

One evaluation is performed on each arriving packet. In each evaluation, if the number of tokens in the bucket is enough, the traffic conforms to the specification and the tokens for forwarding the packet are taken away; if the number of tokens in the bucket is not enough, it means that too many tokens have been used and the traffic is excessive.

The working mechanism of rate limit

This section uses the outgoing packets for example. When rate limit is configured on an interface, a token bucket handles all packets to be sent through the interface for rate limiting. If the token bucket has enough tokens, packets can be forwarded; otherwise, packets are put into QoS queues for congestion management. In this way, the traffic passing the physical interface is controlled.

Figure 480 Rate limit implementation

With a token bucket used for traffic control, when the token bucket has tokens, the bursty packets can be transmitted; if no tokens are available, packets cannot be transmitted until new tokens are generated in the token bucket. In this way, the traffic rate is restricted to the rate for generating tokens, the traffic rate is limited, and bursty traffic is allowed.

Priority mapping

Concepts

When a packet enters a network, it is marked with a certain priority to indicate its scheduling weight or forwarding priority. Then, the intermediate nodes in the network process the packet according to the priority.

When a packet enters a device, the device assigns to the packet a set of predefined parameters (including the 802.1p priority, DSCP values, IP precedence, and local precedence).

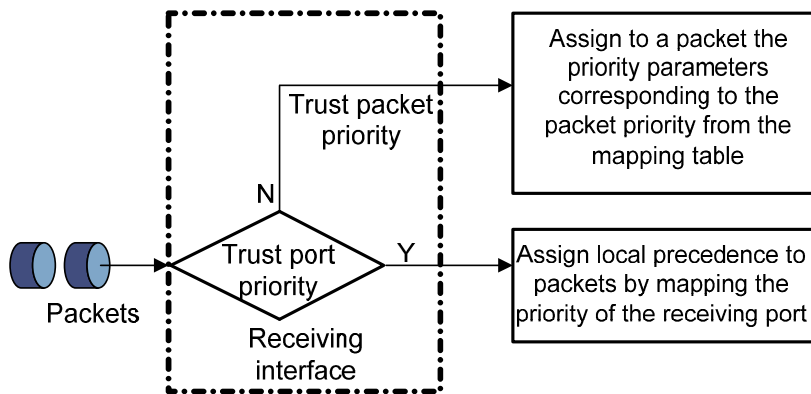

- For more information about 802.1p priority, DSCP values, and IP precedence, see "[Packet precedences](#)."
- Local precedence is a locally significant precedence that the device assigns to a packet. A local precedence value corresponds to an output queue. Packets with the highest local precedence are processed preferentially.

The device provides the following priority trust modes on a port:

- **Trust packet priority**—The device assigns to the packet the priority parameters corresponding to the packet's priority from the mapping table.
- **Trust port priority**—The device assigns a priority to a packet by mapping the priority of the receiving port.

You can select one priority trust mode as needed. [Figure 481](#) shows the process of priority mapping on a device.

Figure 481 Priority mapping process

Introduction to priority mapping tables

The device provides the following types of priority mapping tables:

- **CoS to DSCP**—802.1p-to-DSCP mapping table.
- **CoS to Queue**—802.1p-to-local mapping table.
- **DSCP to CoS**—DSCP-to-802.1p mapping table, which applies to only IP packets.
- **DSCP to DSCP**—DSCP-to-DSCP mapping table, which applies to only IP packets.
- **DSCP to Queue**—DSCP-to-local mapping table, which applies to only IP packets.

[Table 142](#) through [Table 143](#) list the default priority mapping tables.

Table 142 The default CoS to DSCP/CoS to Queue mapping table

Input CoS value	Local precedence (Queue)	DSCP
0	2	0
1	0	8
2	1	16
3	3	24
4	4	32
5	5	40
6	6	48
7	7	56

Table 143 The default DSCP to CoS/DSCP to Queue mapping table

Input DSCP value	Local precedence (Queue)	CoS
0 to 7	0	0
8 to 15	1	1
16 to 23	2	2
24 to 31	3	3
32 to 39	4	4
40 to 47	5	5
48 to 55	6	6
56 to 63	7	7

NOTE:

In the default DSCP to DSCP mapping table, an input value yields a target value equal to it.

Recommended QoS configuration procedures

Recommended QoS policy configuration procedure

A QoS policy involves the following components: class, traffic behavior, and policy. You can associate a class with a traffic behavior using a QoS policy.

1. Class

Classes identify traffic.

A class is identified by a class name and contains some match criteria.

You can define a set of match criteria to classify packets. The relationship between criteria can be **and** or **or**.

- **and**—The device considers a packet belongs to a class only when the packet matches all the criteria in the class.
- **or**—The device considers a packet belongs to a class as long as the packet matches one of the criteria in the class.

2. Traffic behavior

A traffic behavior, identified by a name, defines a set of QoS actions for packets.

3. Policy

You can apply a QoS policy to a port to regulate the inbound or outbound traffic of the port. A QoS policy can be applied to multiple ports. Only one policy can be applied in the inbound direction of a port.

Perform the tasks in [Table 144](#) to configure a QoS policy:

Table 144 Recommended QoS policy configuration procedure

Step	Remarks
1. Adding a class	Required. Add a class and specify the logical relationship between the match criteria in the class.
2. Configuring classification rules	Required. Configure match criteria for the class.
3. Adding a traffic behavior	Required. Add a traffic behavior.
4. Configure actions for the behavior: <ul style="list-style-type: none"> Configuring traffic redirecting for a traffic behavior Configuring other actions for a traffic behavior 	Required. Use either method. Configure various actions for the traffic behavior.
5. Adding a policy	Required. Add a policy.
6. Configuring classifier-behavior associations for the policy	Required. Associate the traffic behavior with the class in the QoS policy. A class can be associated with only one traffic behavior in a QoS policy. Associating a class already associated with a traffic behavior will overwrite the old association.
7. Applying a policy to a port	Required. Apply the QoS policy to a port.

Recommended queue scheduling configuration procedure

Step	Remarks
1. Configuring queue scheduling on a port	Optional. Configure the queue scheduling mode for a port.

Recommended rate limit configuration procedure

Step	Remarks
1. Configuring rate limit on a port	Required. Limit the rate of incoming packets or outgoing packets of a physical port.

Recommended priority mapping table configuration procedure

Step	Remarks
1. Configuring priority mapping tables	Optional. Set priority mapping tables.

Recommended priority trust mode configuration procedure

Step	Remarks
1. Configuring priority trust mode on a port	Required. Set the priority trust mode of a port.

Adding a class

1. Select **QoS > Classifier** from the navigation tree.
2. Click the **Create** tab to enter the page for adding a class.

Configuration guidelines

If an ACL is referenced by a QoS policy for defining traffic classification rules, packets matching the referenced ACL rule are organized as a class and the behavior defined in the QoS policy applies to the class regardless of whether the referenced ACL rule is a **deny** or **permit** clause.

ACL and QoS configuration example

Network requirements

As shown in [Figure 497](#), the FTP server (10.1.1.1/24) is connected to the Switch, and the clients access the FTP server through GigabitEthernet 1/0/1 of the Switch.

Configure an ACL and a QoS policy as follows to prevent the hosts from accessing the FTP server from 8:00 to 18:00 every day:

1. Add an ACL to prohibit the hosts from accessing the FTP server from 8:00 to 18:00 every day.
2. Configure a QoS policy to drop the packets matching the ACL.
3. Apply the QoS policy in the inbound direction of GigabitEthernet 1/0/1.

Figure 497 Network diagram

Configuring Switch

1. Define a time range to cover the time range from 8:00 to 18:00 every day:
 - a. Select **QoS > Time Range** from the navigation tree.
 - b. Click the **Create** tab.
 - c. Enter the time range name **test-time**.
 - d. Select the **Periodic Time Range** box.
 - e. Set the **Start Time** to 8:00 and the **End Time** to 18:00.
 - f. Select the options **Sun** through **Sat**.
 - g. Click **Apply**.

ACL Number	Type	Number of Rules	Match Order

3. Define an ACL rule for traffic to the FTP server:

- a. Click the **Advanced Setup** tab.
- b. Select **3000** from the **ACL** list.
- c. Select the **Rule ID** box, and enter rule ID **2**.
- d. Select **Permit** from the **Action** list.
- e. Select the **Destination IP Address** box, and enter IP address **10.1.1.1** and destination wildcard **0.0.0.0**.
- f. Select **test-time** from the **Time Range** list.
- g. Click **Add**.

Figure 500 Defining an ACL rule for traffic to the FTP server

The screenshot shows the 'Advanced Setup' tab for configuring an ACL rule. The 'ACL' dropdown is set to '3000'. Under 'Configure an Advanced ACL', 'Rule ID' is set to '2' and 'Action' is 'Permit'. The 'Destination IP Address' is '10.1.1.1' and the 'Destination Wildcard' is '0.0.0.0'. The 'Time Range' is set to 'test-time'. The 'Add' button is highlighted in red.

Rule ID	Operation	Description	Time Range

4. Add a class:
 - a. Select **QoS > Classifier** from the navigation tree.

- b. Click the **Create** tab.
- c. Enter the class name **class1**.
- d. Click **Add**.

10. Apply the QoS policy in the inbound direction of interface GigabitEthernet 1/0/1:

- Select **QoS > Port Policy** from the navigation tree.
- Click the **Setup** tab.
- Select **policy1** from the **Please select a policy** list.
- Select **Inbound** from the **Direction** list.
- Select port GigabitEthernet 1/0/1.
- Click **Apply**.

A configuration progress dialog box appears.

- g. Click **Close** when the progress dialog box prompts that the configuration succeeds.

Figure 508 Applying the QoS policy in the inbound direction of GigabitEthernet 1/0/1

The screenshot shows a configuration window with three tabs: 'Summary', 'Setup', and 'Remove'. The 'Setup' tab is active. Below the tabs, there are two dropdown menus: 'Please select a policy' with 'policy1' selected, and 'Direction' with 'Inbound' selected. These two dropdowns are enclosed in a red rectangular box. Below these, the text 'Please select port(s)' is followed by a port selection interface. This interface shows a grid of ports: 1, 3, 5, 7 in the top row and 2, 4, 6, 8 in the bottom row, with a separate box for port 9. Port 1 is highlighted with a red box. To the right of the port grid, the text 'HP 1910-8G-PoE+...' is visible. Below the port selection area are two buttons: 'Select All' and 'Select None'. At the bottom of the window, there is an 'Apply' button, which is also enclosed in a red rectangular box.

Configuring PoE

IEEE 802.3af-compliant power over Ethernet (PoE) enables a power sourcing equipment (PSE) to supply power to powered devices (PDs) through Ethernet interfaces over twisted pair cables. Examples of PDs include IP telephones, wireless APs, portable chargers, card readers, web cameras, and data collectors. A PD can also use a different power source from the PSE at the same time for power redundancy.

A 1910 switch has a built-in PSE to supply DC power to PDs over the data pairs (pins 1, 2 and 3, 6) of category 3/5 twisted pair cable, as shown in [Figure 509](#). In this figure, PI represents PoE Ethernet interfaces.

Figure 509 PoE system

If a PD does not accept power over data pairs, the switch cannot supply power to it.

Restrictions and prerequisites

PoE is available only for PoE switches. For non-PoE switches, PoE related fields and tabs are not available or configurable.

To configure PoE and make the PoE setting take effect, make sure the PoE power supply and the PSE are operating correctly.

Make sure PDs accept power supplied over data pairs of category 3/5 twisted pair cable. If a PD does not support this power supplying mode, change the order of the lines in the cable.

Configuring PoE ports

1. Select **PoE > PoE** from the navigation tree.
2. Click the **Port Setup** tab.

Figure 510 Port Setup tab

Summary PSE Setup **Port Setup**

Select Port:

HP 1910-8G-PoE+...

Select All Select None Note: The "Select All" and the "Select None" are only applied to current unit.

Selected Power Supplied Power Enabled Power Disabled Not Supported Power Fault

Power State: No Change

Power Max: 30000 (1000-30000 milliwatts, step = 100)

Power Priority: No change

Selected Ports:

Apply Cancel

3. Configure the PoE ports as described in [Table 158](#).
4. Click **Apply**.

Table 158 Configuration items

Item	Description
Select Port	Select ports to be configured. They will be displayed in the Selected Ports area.
Power State	<p>Enable or disable PoE on the selected ports.</p> <ul style="list-style-type: none"> System does not supply power to or reserve power for the PD connected to a PoE port if the PoE port is not enabled with the PoE function. You are allowed to enable PoE for a PoE port if the PoE port will not result in PoE power overload; otherwise, you are not allowed to enable PoE for the PoE port. <p>By default, PoE is disabled on a PoE port.</p> <p>! IMPORTANT:</p> <p>PSE power overload—When the sum of the power consumption of all ports exceeds the maximum power of PSE, the system considers the PSE is overloaded.</p>
Power Max	<p>Set the maximum power for the PoE port.</p> <p>Maximum PoE port power is the maximum power that the PoE port can provide to the connected PD. If the power required by the PD is larger than the maximum PoE port power, the PoE port will not supply power to the PD.</p> <p>By default, a PoE port can supply a maximum power of 30,000 milliwatts.</p>

Item	Description
Power Priority	<p>Set the power supply priority for a PoE port. The priority levels of a PoE port include low, high, and critical in ascending order.</p> <ul style="list-style-type: none"> When the PoE power is insufficient, power is first supplied to PoE ports with a higher priority level. When the PSE power is overloaded, the PoE port with a lower priority is first disconnected to guarantee the power supply to the PD with a higher priority. If you set the priority of a PoE port to critical, the system compares the guaranteed remaining PSE power (the maximum PSE power minus the maximum power allocated to the existing critical PoE port, regardless of whether PoE is enabled for the PoE port) with the maximum power of this PoE port. If the former is greater than the latter, you can succeed in setting the priority to critical, and this PoE port will preempt the power of other PoE ports with a lower priority level; otherwise, you will fail to set the PoE port to critical. In the former case, the PoE ports whose power is preempted will be powered off, but their configurations will remain unchanged. When you change the priority of a PoE port from critical to a lower level, the PDs connecting to other PoE ports will have an opportunity of being powered. <p>By default, the power priority of a PoE port is low.</p> <p>! IMPORTANT:</p> <ul style="list-style-type: none"> 19 watts guard band is reserved for each PoE port on the device to prevent a PD from being powered off because of a sudden increase of the PD power. When the remaining power of the PSE is lower than 19 watts, the port with a higher priority can preempt the power of the port with a lower priority to ensure the normal working of the higher priority port. If the sudden increase of the PD power results in PSE power overload, power supply to the PD on the PoE interface with a lower priority will be stopped to ensure the power supply to the PD with a higher priority.

Configuring non-standard PD detection

There are standard PDs and nonstandard PDs. Standard PDs are those conforming to the IEEE 802.3af standard. Usually, the PSE can detect only standard PDs and supply power to them. The PSE can detect nonstandard PDs and supply power to them only after the PSE is enabled to detect nonstandard PDs.

1. Select **PoE > PoE** from the navigation tree.
2. Click the **PSE Setup** tab.

The page displays the location of the PSE, and the status of the non-standard PD detection function.

Figure 511 PSE Setup tab

Summary	PSE Setup	Port Setup
---------	------------------	------------

PSE ID	Location	Non-Standard PD Compatibility
1	slot 1 subslot 0	Disable

Enabling the non-standard PD detection function

Perform one of the following tasks on the **PSE Setup** tab to enable the non-standard PD detection function:

- Select **Enable** in the **Non-Standard PD Compatibility** column, and click **Apply**.
- Click **Enable All**.

Disabling the non-standard PD detection function for a PSE

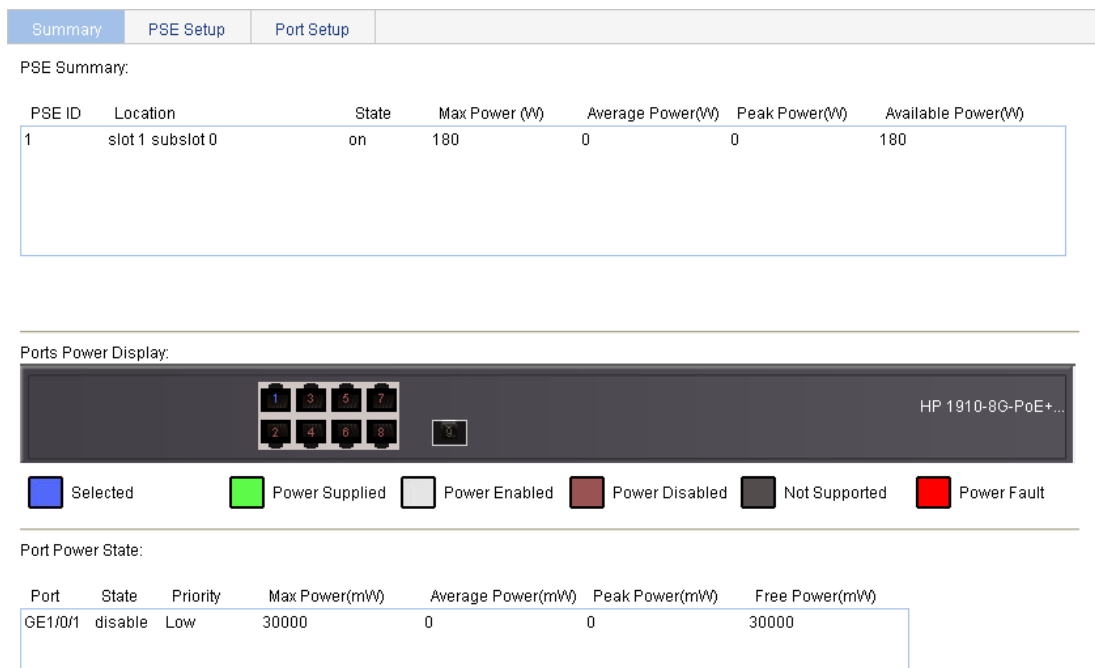

Perform one of the following tasks on the **PSE Setup** tab to disable the non-standard PD detection function:

- Select **Disable** in the **Non-Standard PD Compatibility** column, and click **Apply**.
- Click **Disable All**.

Displaying information about PSE and PoE ports

1. Select **PoE > PoE** from the navigation tree to enter the **Summary** tab.
The upper part of the page displays the PSE summary.
2. To view the configuration and power information, click a port on the chassis front panel.

Figure 512 Summary tab (with GigabitEthernet 1/0/1 selected)

PoE configuration example

Network requirements

As shown in [Figure 513](#), GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 are connected to IP telephones.

GigabitEthernet 1/0/3 is connected to AP whose maximum power does not exceed 9000 milliwatts.

The power supply priority of IP telephones is higher than that of AP; therefore, the PSE supplies power to IP telephones first when the PSE power is overloaded.

Figure 513 Network diagram

Configuration procedure

1. Enable PoE on GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2, and set their power supply priority to **critical**:
 - a. Select **PoE > PoE** from the navigation tree.
 - b. Click the **Setup** tab.
 - c. On the tab, click to select ports GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 from the chassis front panel, select **Enable** from the **Power State** list, and select **Critical** from the **Power Priority** list.
 - d. Click **Apply**.

Figure 514 Configuring the PoE ports supplying power to the IP telephones

Summary PSE Setup Port Setup

Select Port:

HP 1910-8G-PoE+...

Select All Select None Note: The "Select All" and the "Select None" are only applied to current unit.

☒ Selected ☒ Power Supplied ☐ Power Enabled ☐ Power Disabled ☐ Not Supported ☐ Power Fault

Power State: Enable

☐ Power Max: (1000-30000 milliwatts, step = 100)

Power Priority: Critical

Selected Ports:

GE1/0/1-GE1/0/2

Apply Cancel

2. Enable PoE on GigabitEthernet 1/0/3 and set the maximum power of the port to 9000 milliwatts:
 - a. Click the **Setup** tab.
 - b. On the tab, click to select port GigabitEthernet 1/0/3 from the chassis front panel, select **Enable** from the **Power State** list, and select the box before **Power Max** and enter **9000**.

c. Click **Apply**.

Figure 515 Configuring the PoE port supplying power to AP

The screenshot displays a network configuration interface for PoE (Power over Ethernet) settings. At the top, there are tabs for 'Summary', 'PSE Setup', and 'Port Setup', with 'Port Setup' being the active tab. Below the tabs, the 'Select Port:' section shows a grid of 8 ports (1-8) with port 3 highlighted in blue. To the right of the grid, the text 'HP 1910-8G-PoE+...' is visible. Below the port grid, there are two buttons: 'Select All' and 'Select None'. A note states: 'Note: The "Select All" and the "Select None" are only applied to current unit.' Below this, a legend shows color-coded boxes for 'Selected' (blue), 'Power Supplied' (green), 'Power Enabled' (grey), 'Power Disabled' (dark red), 'Not Supported' (black), and 'Power Fault' (red). The 'Power State:' dropdown is set to 'Enable'. The 'Power Max:' field is set to '9000' with a checkmark icon, and a note indicates '(1000-30000 milliwatts, step = 100)'. The 'Power Priority:' dropdown is set to 'No change'. Below these settings, the 'Selected Ports:' section shows a list box containing 'GE1/0/3'. At the bottom right, there are 'Apply' and 'Cancel' buttons.

Summary PSE Setup **Port Setup**

Select Port:

HP 1910-8G-PoE+...

Select All Select None Note: The "Select All" and the "Select None" are only applied to current unit.

Selected Power Supplied Power Enabled Power Disabled Not Supported Power Fault

Power State: Enable

Power Max: 9000 (1000-30000 milliwatts, step = 100)

Power Priority: No change

After the configuration takes effect, the IP telephones and the AP are powered and can work correctly.

Support and other resources

Contacting HP

For worldwide technical support information, see the HP support website:

<http://www.hp.com/support>

Before contacting HP, collect the following information:

- Product model names and numbers
- Technical support registration number (if applicable)
- Product serial numbers
- Error messages
- Operating system type and revision level
- Detailed questions

Subscription service

HP recommends that you register your product at the Subscriber's Choice for Business website:

<http://www.hp.com/go/wwalerts>

After registering, you will receive email notification of product enhancements, new driver versions, firmware updates, and other product resources.

Related information

Documents

To find related documents, browse to the Manuals page of the HP Business Support Center website:

<http://www.hp.com/support/manuals>

- For related documentation, navigate to the Networking section, and select a networking category.
- For a complete list of acronyms and their definitions, see *HP FlexNetwork Technology Acronyms*.

Conventions

This section describes the conventions used in this documentation set.

Command conventions

Convention	Description
Boldface	Bold text represents commands and keywords that you enter literally as shown.
<i>Italic</i>	<i>Italic</i> text represents arguments that you replace with actual values.
[]	Square brackets enclose syntax choices (keywords or arguments) that are optional.
{ x y ... }	Braces enclose a set of required syntax choices separated by vertical bars, from which you select one.
[x y ...]	Square brackets enclose a set of optional syntax choices separated by vertical bars, from which you select one or none.
{ x y ... } *	Asterisk-marked braces enclose a set of required syntax choices separated by vertical bars, from which you select at least one.
[x y ...] *	Asterisk-marked square brackets enclose optional syntax choices separated by vertical bars, from which you select one choice, multiple choices, or none.
&<1-n>	The argument or keyword and argument combination before the ampersand (&) sign can be entered 1 to n times.
#	A line that starts with a pound (#) sign is comments.

GUI conventions

Convention	Description
Boldface	Window names, button names, field names, and menu items are in bold text. For example, the New User window appears; click OK .
>	Multi-level menus are separated by angle brackets. For example, File > Create > Folder .

Symbols

Convention	Description
 WARNING	An alert that calls attention to important information that if not understood or followed can result in personal injury.
 CAUTION	An alert that calls attention to important information that if not understood or followed can result in data loss, data corruption, or damage to hardware or software.
 IMPORTANT	An alert that calls attention to essential information.
NOTE	An alert that contains additional or supplementary information.
 TIP	An alert that provides helpful information.

Network topology icons

	Represents a generic network device, such as a router, switch, or firewall.
	Represents a routing-capable device, such as a router or Layer 3 switch.
	Represents a generic switch, such as a Layer 2 or Layer 3 switch, or a router that supports Layer 2 forwarding and other Layer 2 features.
	Represents an access controller, a unified wired-WLAN module, or the switching engine on a unified wired-WLAN switch.
	Represents an access point.
	Represents a security product, such as a firewall, a UTM, or a load-balancing or security card that is installed in a device.
	Represents a security card, such as a firewall card, a load-balancing card, or a NetStream card.

Port numbering in examples

The port numbers in this document are for illustration only and might be unavailable on your device.
